**Abstract:** *Peucedanum japonicum* (Umbelliferae) is widely distributed throughout Southeast Asian countries. The root of this plant is used in traditional medicine to treat colds and pain, whereas the young leaves are considered an edible vegetable. In this study, the differences in coumarin profiles for different parts of *P. japonicum* including the flowers, roots, leaves, and stems were compared using ultra-performance liquid chromatography time-of-flight mass spectrometry. Twenty-eight compounds were tentatively identified, including three compounds found in the genus *Peucedanum* for the first time. Principal component analysis using the data set of the measured mass values and intensities of the compounds exhibited distinct clustering of the flower, leaf, stem, and root samples. In addition, their anticancer activities were screened using an Aldo–keto reductase (AKR)1C1 assay on A549 human non-small-cell lung cancer cells and the flower extract inhibited AKR1C1 activity. Based on these results, seven compounds were selected as potential markers to distinguish between the flower part versus the root, stem, and leaf parts using an orthogonal partial least-squares discriminant analysis. This study is the first to provide information on the comparison of coumarin profiles from different parts of *P. japonicum* as well as their AKR1C1 inhibitory activities. Taken together, the flowers of *P. japonicum* offer a new use related to the efficacy of overcoming anticancer drug resistance, and may be a promising source for the isolation of active lead compounds.

**Keywords:** *Peucedanum japonicum*; coumarin; Aldo–keto reductases

## 1. Introduction

*Peucedanum japonicum* Thunb. (Umbelliferae) is widely distributed in Korea, Japan, China, and Taiwan [1]. In the records of the traditional medicinal uses of *P. japonicum* in Southeast Asia, the stem and root have been used to treat sore throat [2], whereas the root has been used to treat cough, colds, and headache, and exhibits antipyretic and anti-inflammatory activity [3–5]. Coumarins are characteristic compounds of *P. japonicum* and several types of coumarins have been identified in this plant, such as simple coumarins, linear furanocoumarins, linear dihydro furanocoumarins, angular furanocoumarins, angular dihydrofuranocoumarins, linear dihydropyranocoumarins, and angular dihydropyranocoumarins [1,6,7]. Other constituents include chrome, phenolic compounds, and flavonoids [1]. The essential oil extracted from the aerial parts of *P. japonicum* contains  $\alpha$ -pinene (24.68%) and  $\beta$ -pinene (66.07%) [5]. Various biological activities reported from the extracts and constituents of *P. japonicum*, such as antioxidant, anti-tyrosinase, anti-microbial,

anti-allergic, neuroprotective, antidiabetic, and antiplatelet aggregative effects, have been summarized in Sarkhail et al., 2014 [1]. Other recent reports of in vitro and in vivo activities include anticancer [8], anti-adipogenic [9], antidiabetic [9], anti-osteoporosis [10], anti-allergic lung inflammation [11], antinociceptive [12], prostate contraction inhibitory [13], anti-osteoarthritis [14], antioxidant [15], anti-obesity [16], endothelial dysfunction improvement [17], anti-Alzheimer's disease [18], corneal damage treatment [19], anti-atopic dermatitis [20], anti-inflammatory [21,22], and anti-influenza virus [23] effects.

Drug resistance is a major obstacle to the overall effectiveness of chemotherapy. Aldo-keto reductases (AKRs), which consist of the AKR1C1-AKR1C4 members, play a pivotal role in nicotinamide-adenine dinucleotide phosphate (NADPH)-dependent reduction and are involved in biosynthesis, intermediate metabolism, and detoxification [24,25]. With respect to the catalytic-dependent function of AKR1C isoforms in cancer chemotherapy, AKRs mediate the reduction of carbonyl groups in anticancer drugs (e.g., daunorubicin, doxorubicin, and oracin) to their inactive metabolites, thus contributing to drug resistance [26–29]. In addition, AKR1C1 is associated with cisplatin-resistance in colon cancer cell, head and neck squamous cell carcinoma, nasopharyngeal carcinoma, and paediatric T-cell acute lymphoblastic leukemia [30–33]. It has been recently reported that AKR1C3 mediates chemotherapy resistance in breast cancer and esophageal adenocarcinoma [34,35]. Thus, AKR1C isoforms may be a potential target for preventing the development of anticancer drug resistance. Moreover, AKR1C1 plays a role in regulating the cellular concentration of progesterone by catalyzing the reduction of progesterone to its inactive form, 20-alpha-hydroxy-progesterone, thus it is also considered a drug target for the prevention of pre-term birth throughout the inhibition of progesterone metabolism mediated by AKR1C1 [36].

In our work to identify AKR1C1 inhibitors from natural products to overcome cisplatin-resistance in human non-small lung cancer cells (NSCLC), the chemical composition of the extracts from four parts of *P. japonicum* and their AKR1C1 inhibitory activities in NSCLC (A549) were examined. Ultra-performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry (UPLC-QToF MS) and multivariate analysis was used to characterize the metabolomic differences between the four extracts.

## 2. Results and Discussion

### 2.1. Identification of Coumarins in the Different Parts of *P. japonicum* Using UPLC-QToF MS

Four parts of *P. japonicum* (flowers, roots, leaves, and stems) were prepared with six samples from each source that were designated as follows: S1–S6 for flower, S13–S18 for root, S7–S12 for leaf, S19–S24 for stem parts. Using UPLC-QToF MS with a gradient solvent system of acetonitrile (containing 0.1% formic acid) and water (containing 0.1% formic acid), the metabolites of the 24 *P. japonicum* samples were separated at high resolution within 22 min in the base peak ion (BPI) chromatogram. The representative BPI chromatograms of the methanol extract of flower, root, leaf, and stem of *P. japonicum* are shown in Figure 1. In these BPI chromatograms, the flower extract exhibited the most peaks and was fractionated using dichloromethane to obtain a chromatogram with increased intensity of coumarins (Figure S1). The mass spectrum of each peak in the BPI chromatogram of the dichloromethane fraction of the *P. japonicum* flowers (Figures S2–S29) was carefully interpreted by analyzing its experimental and theoretical high-resolution MS (the positive mode), error ppm, molecular formula, and MS/MS fragmentation (Table 1), as well as by comparing with existing data for coumarins of the *Peucedanum* species reported in the literature [3,6,37–53]. In addition, UPLC-PDA chromatograms of all the peaks present in the methanol extract of four parts of *P. japonicum* and their UV-Vis spectra between 210–500 nm were shown in Figures S30 and S31. The coumarin structures, which were tentatively identified from the analysis of their MS data, are shown in Figure 2.

<sup>1</sup> Identified molecules with the same superscript letters (a–f) are interchangeable.

**Figure 2.** Structures of identified coumarins (Peaks 1–28).

In the ion fragmentation pathways of angular dihydropyranocoumarins, such as khellactone (3,4,5-trihydroxy-2,2-dimethyl-6-chromanacrylic acid  $\delta$ -lactone), the MS fragment peak of the molecules resulting from a loss of the C-4' substituent was observed as the main peak and the molecular ion peak due to fragmentation of the C-3' substituent was small or undetectable [6]. Based on this phenomenon, we concluded that the position of the C-3' and C-4' substituents could be determined by MS fragmentation. In this study, molecular ions for angular dihydropyranocoumarins also exhibited characteristic fragment ions of  $[M-R_2OH+H]^+$  by the loss of the C-4' substituent, and  $[M-R_2OH-(R_1-H)+H]^+$  and  $[M-R_2OH-(OR_1-H)+H]^+$  by the loss of the C-3' substituent. Therefore, in the ion fragmentation pathways of angular dihydropyranocoumarins, fragment ions at  $m/z$  245.08  $[M-R_2OH-(R_1-H)+H]^+$  for 5-hydroxy-2,2-dimethyl-3-oxo-6-chromanacrylic acid  $\delta$ -lactone (jatamasinone) and 227.07  $[M-R_2OH-(OR_1-H)+H]^+$  for 5-hydroxy-2,2-dimethyl-3,4-didehydro-6-chromanacrylic acid  $\delta$ -lactone were frequently observed. Peak 5 ( $t_R$  7.878 min) showed a molecular ion at  $m/z$  383.1159  $[M + Na]^+$  (calculated for  $C_{19}H_{20}O_7Na^+$ , 383.1107) and fragment ions at  $m/z$  287.0963  $[M-R_2OH+H]^+$ , 245.0847  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0740  $[M-R_2OH-(OR_1-H)+H]^+$ , indicating the presence of a propionate group at C-4' and an acetate group at C-3'. Thus, peak 5 was identified as 3'-O-acetyl-4'-O-propanoylkhellactone, which was first detected in *P. japonicum*; however, it has also

been isolated from *P. prearuptorum* [41]. Peak 6 ( $t_R$  8.261 min) produced a major molecular ion at  $m/z$  369.1314  $[M + Na]^+$  (calculated for  $C_{19}H_{22}O_6Na^+$ , 369.1314) and yielded fragment ions at  $m/z$  329.1384  $[M-R_2OH+H]^+$  and 245.0814  $[M-R_2OH-(R_1-H)+H]^+$ , indicating the presence of a hydroxyl group at C-4' and a 2-methyl butanoate or isovalerate group at C-3'. Therefore, peak 6 was tentatively identified as 3'-O-(2-methyl-butyl)-4'-hydroxy khellactone, which was isolated from *P. japonicum* [6] or 3'-O-(isovaleryl)-4'-hydroxy khellactone, which was isolated from *P. turgeniifolium* [42], but not *P. japonicum*. Peak 7 ( $t_R$  9.667 min) showed a molecular ion at  $m/z$  397.1269  $[M + Na]^+$  (calculated for  $C_{20}H_{22}O_7Na^+$ , 397.1263), which is 14 Da greater than that of peak 5, with fragment ions at  $m/z$  287.0924  $[M-R_2OH+H]^+$ , showing the presence of the isobutyrate group at C-4'. The fragment ions at  $m/z$  245.0802  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0709  $[M-R_2OH-(OR_1-H)+H]^+$  indicate the presence of the acetate group at C-3'. Thus, peak 7 was identified as 3'-O-acetyl-4'-O-isobutyryl khellactone, which was first detected in *P. japonicum*; however, it has also been isolated from *P. prearuptorum* [43]. Peaks 9 ( $t_R$  10.581 min) and 10 ( $t_R$  10.678 min) yielded identical molecular ions at  $m/z$  409.1266  $[M + Na]^+$  (calculated for  $C_{21}H_{22}O_7Na^+$ , 409.1263) and identical fragment ions to one another at  $m/z$  287.0916  $[M-R_2OH+H]^+$ , 245.0814  $[M-R_2OH-(R_1-H)+H]^+$ , and 227.0707  $[M-R_2OH-(OR_1-H)+H]^+$ , indicating the presence of an angeloate or a senecioate group at C-4' and an acetate group at C-3'. Therefore, peaks 9 and 10 were tentatively identified as 3'-O-acetyl-4'-O-angeloylkhellactone and 3'-O-acetyl-4'-O-seneciolykhellactone, respectively, but they are interchangeable. In addition, both compounds were isolated from *P. japonicum* [38]. Peak 11 ( $t_R$  11.987 min) yielded a major molecular ion at  $m/z$  411.1419  $[M + Na]^+$  (calculated for  $C_{21}H_{24}O_7Na^+$ , 411.1420) and a fragment ion at  $m/z$  287.0921  $[M-R_2OH+H]^+$ , suggesting the presence of the 2-methyl butanoate or isovalerate groups at C-4'. The fragment ions at  $m/z$  245.0820  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0715  $[M-R_2OH-(OR_1-H)+H]^+$  indicated that the acetate group was substituted at C-3'. Therefore, peak 11 was tentatively identified as 3'-O-acetyl-4'-O-(2-methyl butanoate)khellactone [6] or 3'-O-acetyl-4'-O-isovalerylkhellactone [44], both of which have been isolated from *P. japonicum* [6,44]. Peak 12 ( $t_R$  13.181 min) produced a major molecular ion at  $m/z$  423.1532  $[M + Na]^+$  (calculated for  $C_{22}H_{24}O_7Na^+$ , 423.1420) and yielded fragment ions at  $m/z$  301.1155  $[M-R_2OH+H]^+$ , indicating the presence of the angeloate or a senecioate group at C-4'. The fragment ions at  $m/z$  245.0878  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0769  $[M-R_2OH-(OR_1-H)+H]^+$  suggested a propionate group at C-3'. Thus, peak 12 was tentatively identified as 3'-O-propanoyl-4'-O-angeloyl khellactone or 3'-O-propanoyl-4'-O-seneciolykhellactone, both of which have not been previously reported. Peak 13 ( $t_R$  13.433 min) produced a major molecular ion at  $m/z$  423.1539  $[M + Na]^+$  (calculated for  $C_{22}H_{24}O_7Na^+$ , 423.1420) and yielded fragment ions at  $m/z$  327.1321  $[M-R_2OH+H]^+$ , indicating the presence of a propionate group at C-4'. The fragment ions at  $m/z$  245.0879  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0769  $[M-R_2OH-(OR_1-H)+H]^+$  suggested the presence of the angeloate or the senecioate group at C-3'. Thus, peak 13 was tentatively identified as 3'-O-angeloyl-4'-O-propanoylkhellactone or 3'-O-senecioly-4'-O-propanoylkhellactone, both of which have been previously reported in a profiling study of pyranocoumarins in *P. prearuptorum* [45]; however, these molecules were first detected in *P. japonicum*. Peak 14 ( $t_R$  14.542 min) produced a molecular ion at  $m/z$  425.1577  $[M + Na]^+$ , corresponding to the molecular formula  $C_{22}H_{26}O_7Na^+$ . The fragment ions at  $m/z$  315.1229  $[M-R_2OH+H]^+$ , 245.0810  $[M-R_2OH-(R_1-H)+H]^+$ , and 227.0710  $[M-R_2OH-(OR_1-H)+H]^+$  indicated the presence of two isobutyrate groups at C-3' and C-4'. As a result, peak 14 was tentatively identified as 3',4'-O-diisobutyrylkhellactone. 3',4'-O-Diisobutyrylkhellactone has not been detected in *P. japonicum*; however, it has been isolated from *Glehnia littoralis* [46] and *Phlojodicarpus sibiricus* [47]. Peaks 15 ( $t_R$  15.319 min) and 18 ( $t_R$  15.885 min) produced identical molecular ions at  $m/z$  437.1574  $[M + Na]^+$  (calculated for  $C_{23}H_{26}O_7Na^+$ , 437.1576) and identical fragmentation patterns. The fragment ion at  $m/z$  327.1227  $[M-R_2OH+H]^+$  indicated the presence of an isobutyrate group at C-4'. The fragment ions at  $m/z$  245.0810  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0710  $[M-R_2OH-(OR_1-H)+H]^+$  were observed as small peaks; however,

they indicated the presence of the angeloate or senecioate group at C-3'. Therefore, peaks 15 and 18 were tentatively identified as 3'-O-angeloyl-4'-O-isobutyrylkhellactone [45,48] and 3'-O-seneciyl-4'-O-isobutyrylkhellactone [49], respectively, but they are interchangeable. Both structures have not been found in *P. japonicum*; however, they were reported in *P. prearuptorum* [45,48,49]. Peaks 16 ( $t_R$  15.442 min) and 17 ( $t_R$  15.667 min) produced the same molecular ion at  $m/z$  437.1577  $[M + Na]^+$  (calculated for  $C_{23}H_{26}O_7Na^+$ , 437.1576) as peaks 15 and 18, but exhibited different a fragment ion at  $m/z$  315.1229  $[M-R_2OH+H]^+$ , suggesting the existence of the angeloate or senecioate group at C-4'. The fragment ions at  $m/z$  245.0813  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0702  $[M-R_2OH-(OR_1-H)+H]^+$  indicated the presence of an isobutyrate group at C-3'. Thus, peaks 16 and 17 were tentatively identified as 3'-O-isobutyryl-4'-O-angeloylkhellactone and 3'-O-isobutyryl-4'-O-seneciylkhellactone, respectively, but they are interchangeable. Both structures have not been identified in *P. japonicum*; however, they have been reported in a study profiling pyranocoumarins in *P. prearuptorum* [45]. Peaks 19 ( $t_R$  16.016 min), 20 ( $t_R$  16.365 min), 21 ( $t_R$  16.747 min), and 22 ( $t_R$  16.993 min) produced identical molecular ions at  $m/z$  449.1585  $[M + Na]^+$  (calculated for  $C_{24}H_{26}O_7Na^+$ , 449.1576) and identical fragment ions at  $m/z$  327.1234  $[M-R_2OH+H]^+$ , indicating the presence of the angeloate or senecioate group at C-4'. The fragment ions at  $m/z$  245.0814  $[M-R_2OH-(R_1-H)+H]^+$  and  $m/z$  227.0705  $[M-R_2OH-(OR_1-H)+H]^+$  resulting from the fragmentation of the C-3' substituent were observed as small peaks; however, this suggested the presence of the angeloate or senecioate group at C-3'. As a result, peaks 19–22 were tentatively identified as 3',4'-O-diangeloylkhellactone, 3'-O-angeloyl-4'-O-seneciylkhellactone, 3',4'-O-diseneciylkhellactone, and 3'-O-seneciyl-4'-O-angeloylkhellactone, respectively, but they are interchangeable. 3'-O-seneciyl-4'-O-angeloylkhellactone has not been found in *P. japonicum*; however, it has been reported in *P. prearuptorum* [48], whereas 3',4'-O-diangeloylkhellactone [50], 3'-O-Angeloyl-4'-O-seneciylkhellactone [44], and 3',4'-O-diseneciylkhellactone [51] have been isolated from *P. japonicum*. Peaks 23 ( $t_R$  17.273 min) and 24 ( $t_R$  17.542 min) yielded identical molecular ions at  $m/z$  439.1729  $[M + Na]^+$  (calculated for  $C_{23}H_{28}O_7Na^+$ , 439.1733). The fragment ions at  $m/z$  329.1384  $[M-R_2OH+H]^+$  were observed by the loss of an isobutyrate group at C-4'. The fragment ions at  $m/z$  245.0814  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0706  $[M-R_2OH-(OR_1-H)+H]^+$  also indicated the presence of the 2-methyl butyrate or isovalerate group at C-3'. Therefore, peaks 23 and 24 were tentatively identified as 3'-O-(2-methyl butyryl)-4'-O-isobutyrylkhellactone and 3'-O-isovaleryl-4'-O-isobutyrylkhellactone, respectively, but they are interchangeable. 3'-O-(2-Methyl butyryl)-4'-O-isobutyrylkhellactone has been isolated from *P. japonicum* [6] and 3'-O-isovaleryl-4'-O-isobutyrylkhellactone has not; however, they have been reported in a profiling study of pyranocoumarins in *P. prearuptorum* [45]. Peak 25 ( $t_R$  18.371 min) showed a molecular ion at  $m/z$  451.1734  $[M + Na]^+$ , corresponding to the molecular formula  $C_{24}H_{28}O_7Na^+$ . The fragment ions at  $m/z$  329.1386  $[M-R_2OH+H]^+$  were observed by the loss of the angeloate or senecioate group at C-4', and the fragment ions at  $m/z$  245.0815  $[M-R_2OH-(R_1-H)+H]^+$ , and 227.0707  $[M-R_2OH-(OR_1-H)+H]^+$  indicated the presence of the 2-methyl butyrate or isovalerate group at C-3'. Therefore, peak 25 was tentatively identified as a molecule among the four structures: 3'-O-(2-methyl butyryl)-4'-O-angeloylkhellactone, 3'-O-(2-methyl butyryl)-4'-O-seneciyl khellactone, 3'-O-isovaleryl-4'-O-angeloylkhellactone, and 3'-O-isovaleryl-4'-O-seneciylkhellactone. 3'-O-(2-Methyl butyryl)-4'-O-seneciyl khellactone [6], 3'-O-isovaleryl-4'-O-seneciylkhellactone [51], and 3'-O-isovaleryl-4'-O-angeloylkhellactone (paeruptorin C) [6] have been isolated from *P. japonicum*. 3'-O-(2-Methyl butyryl)-4'-O-angeloylkhellactone [52] has not been found in *P. japonicum*; however, it has been identified in *P. prearuptorum* [52]. Peak 26 ( $t_R$  18.799 min) exhibited the same molecular ion at  $m/z$  451.1731  $[M + Na]^+$  as peak 25, which corresponded to the molecular formula  $C_{24}H_{28}O_7Na^+$ ; however, the fragment ions at  $m/z$  327.1237  $[M-R_2OH+H]^+$  indicated that peaks 25 and 26 had substituents different from the substituent at C-4' from the loss of the 2-methyl butyrate or isovalerate group at C-4'. The fragment ions at  $m/z$  245.0819  $[M-R_2OH-(R_1-H)+H]^+$  and 227.0710  $[M-R_2OH-(OR_1-H)+H]^+$  suggested the presence of an angeloate or senecioate group at C-3'. There-

fore, peak 26 was tentatively identified as a molecule among the four structures, 3'-O-angeloyl-4'-O-(2-methyl butyryl)khellactone, 3'-O-angeloyl-4'-O-isovaleryl khellactone, 3'-O-senecioid-4'-O-(2-methyl butyryl)khellactone, or 3'-O-senecioid-4'-O-isovaleryl khellactone. 3'-O-Angeloyl-4'-O-(2-methyl butyryl)khellactone [53] and 3'-O-angeloyl-4'-O-isovalerylkhellactone [53] have not been found in *P. japonicum*; however, they have been isolated from *P. prearuptorum* [53]. 3'-O-Senecioid-4'-O-(2-methyl butyryl)khellactone [6] and 3'-O-senecioid-4'-O-isovalerylkhellactone [3] have been isolated from *P. japonicum*. Peaks 27 ( $t_R$  20.919 min) and 28 ( $t_R$  21.268 min) produced the same molecular ion at  $m/z$  453.1896  $[M + Na]^+$  (calculated for  $C_{24}H_{30}O_7Na^+$ , 453.1889) and exhibited an identical fragment ion at  $m/z$  329.1392  $[M-R_2OH+H]^+$ ,  $m/z$  245.0817  $[M-R_2OH-(R_1-H)+H]^+$ , and  $m/z$  227.0708  $[M-R_2OH-(OR_1-H)+H]^+$ , suggesting the presence of a 2-methyl butyrate or isovalerate group at C-4' and a 2-methyl butyrate or isovalerate group at C-3'. Thus, peaks 27 and 28 were tentatively identified as two molecules among the four structures: 3',4'-O-di(2-methyl butyryl)khellactone, 3'-O-(2-methyl butyryl)-4'-O-isovalerylkhellactone, 3'-O-isovaleryl-4'-O-(2-methyl butyryl)khellactone, or 3',4'-O-diisovalerylkhellactone. 3',4'-O-Di(2-methyl butyryl)khellactone [53], 3'-O-(2-methyl butyryl)-4'-O-isovalerylkhellactone [52], and 3'-O-isovaleryl-4'-O-(2-methyl butyryl)khellactone [53] have not been found in *P. japonicum*; however, they have been identified previously in *P. prearuptorum* [52,53], whereas 3',4'-O-diisovalerylkhellactone has been isolated from *P. japonicum* [51].

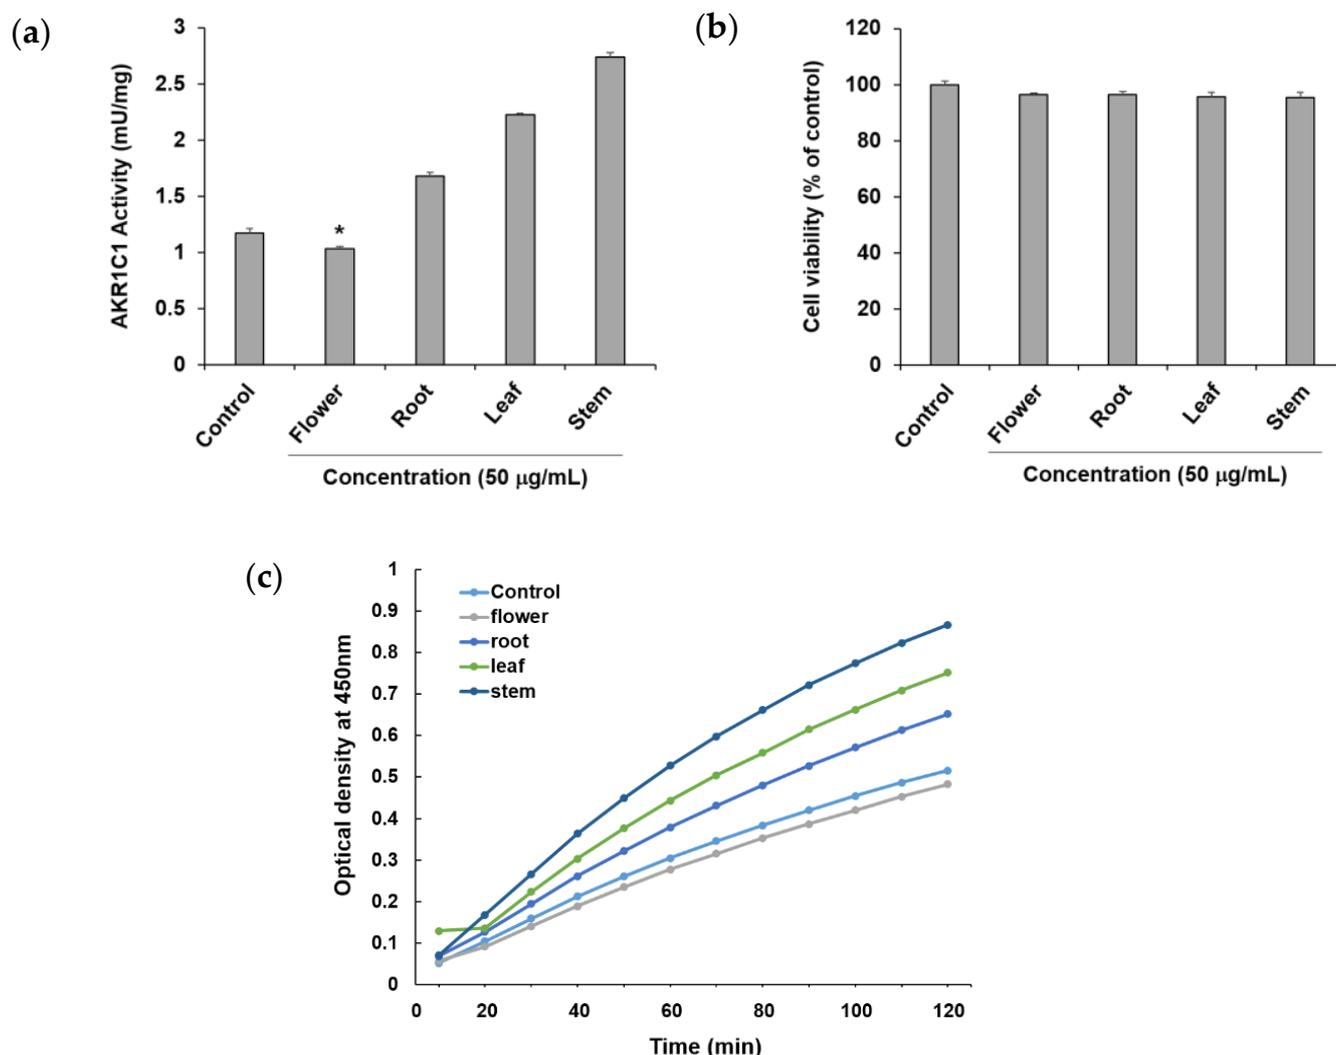

## 2.2. Aldo-Keto Reductases Inhibitory Effects of the Different Parts for *P. japonicum*

To confirm the ability of methanol extracts of four different parts of *P. japonicum*, flower (S1–S3), root (S13–S15), leaf (S7–S9), and stem (S19–S21), to circumvent anticancer drug resistance, they were tested using an in vitro AKR1C1 activity assay. Among the four extracts, the flower extract exhibited AKR1C1 activity inhibition of  $11.74 \pm 0.48\%$  at a concentration of 50  $\mu\text{g}/\text{mL}$  without causing cytotoxicity, whereas the other extracts increased AKR1C1 activity (Figure 3a). By observing optical density over time, the flower extract also showed a lower value compared with the control (Figure 3c). Thus, the flower extract was considered a potential natural source for compounds that prevent or overcome anticancer drug resistance in cancer. In the current reports of AKR1C1 inhibitors, non-competitive inhibitors include benzodiazepines, such as medazepam, phthalimide, pyrimidine, and anthranilic acid derivatives [54]. The representative competitive inhibitor of AKR1C1 is 3-bromo-5-phenylsalicylic acid [55]. Efforts for the development of AKR1C1 inhibitors are continuing through molecular docking and in vitro enzymatic studies using a number of synthetic compound derivatives [56–58]; however, there have been few reports of AKR1C1 inhibitors developed from natural products [59,60]. Therefore, the flower extract could be a promising source for the isolation of active lead compounds that inhibit AKR1C1 activity.

## 2.3. Multivariate Analysis

This study compared the differences in coumarin composition between the flowers, roots, leaves, and stems of *P. japonicum*. Using UPLC-QToF MS, the extracts from four different parts were analyzed. Twenty-four samples, six from each part containing 26 coumarins, were included in the multivariate analysis comparison study (peaks 2 and 5 were not included because they were not detected in methanol extracts). Principal component analysis (PCA) clearly distinguished flower (S1–S6), root (S13–S18), leaf (S7–S12), and stem (S19–S24) samples. As shown in Figure 4, leaf (S7–S12) and stem (S19–S24) samples clustered into one large group. PCA was conducted with three principal components (PC1–PC3) that described the variation, 0.913% R2X, and predictive capability, 0.826% Q2. Eigenvalues for PC1 and PC2 were 15.9 and 4.98, respectively, indicating that these first two principal components account for a substantial amount of the data variance. The relatively smaller eigenvalue of PC3 (0.996) led us to select only PC1 and PC2 for further examination. The first two principal components accounted for 87.2% of the variance (66.4% and 20.8% by PC1 and PC2, respectively). The corresponding PCA loading plot (Figure 4b) revealed that

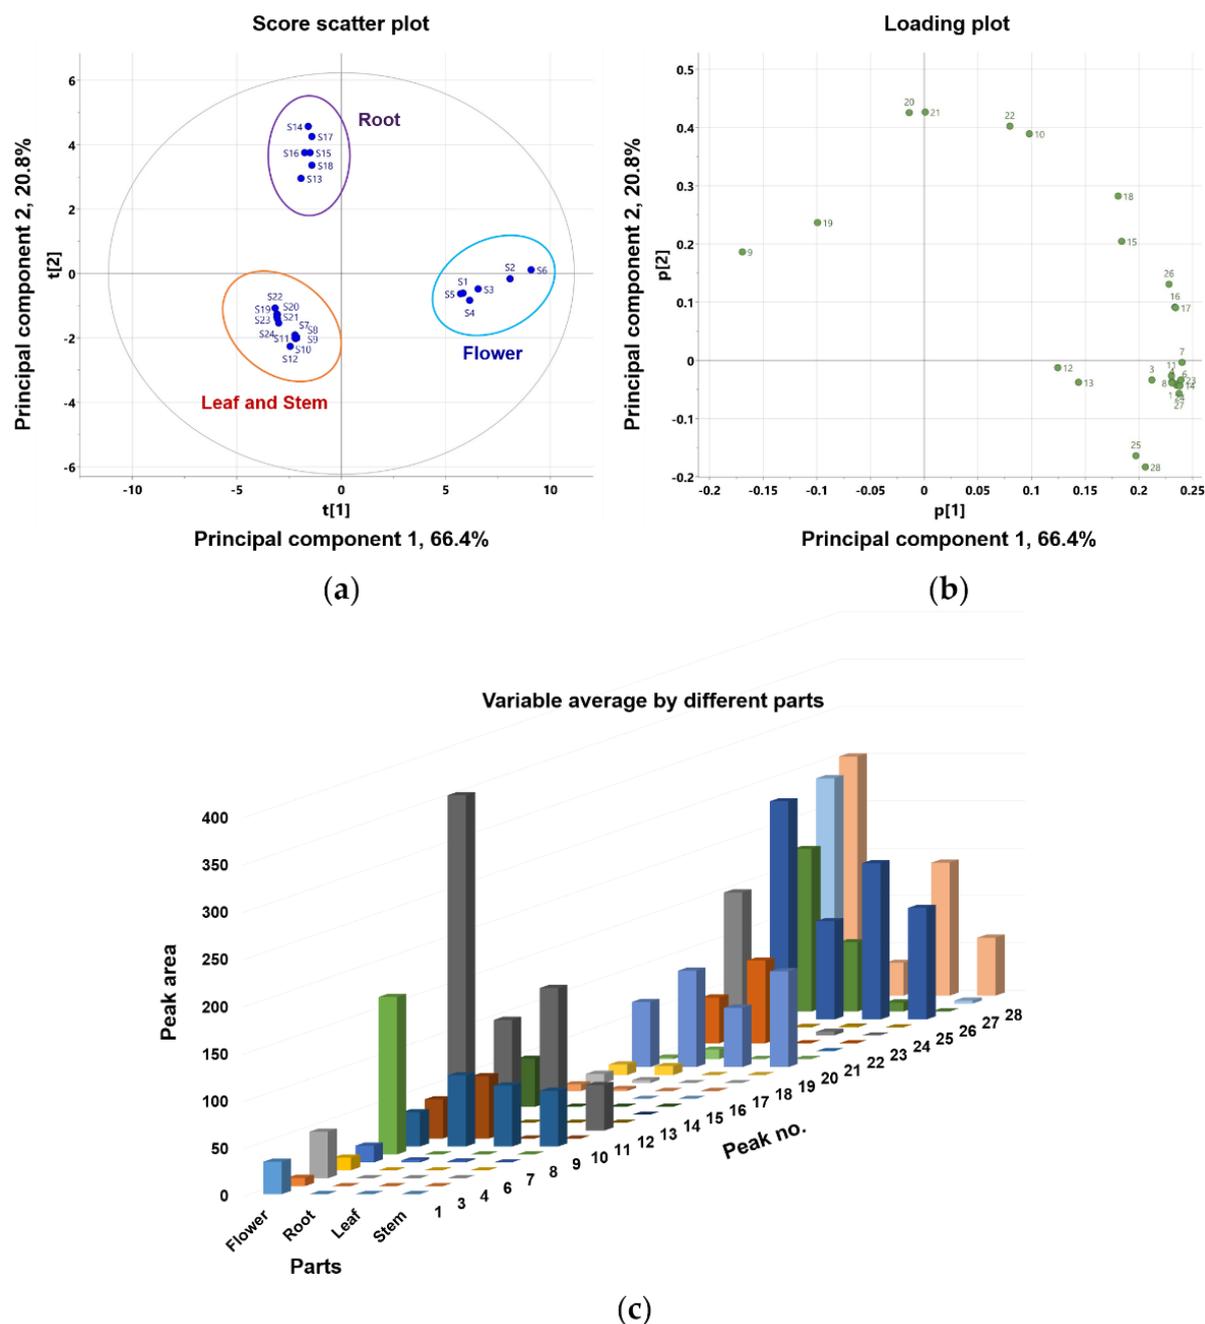

most of the peaks were coumarins, except for peaks 9, 10, and 19–21, which were chemical markers responsible for separating the flower sample from the root, leaf, and stem samples. Based on the PCA values, the coumarin profiles for the four parts of *P. japonicum* were distinct. Moreover, a variable average by different parts (Figure 4c) also clearly showed that most identified coumarins are abundant in the flower part compared with the root, leaf, and stem parts. Finally, leaves and stems share a chemical profile that is distinct from that of roots and flowers.

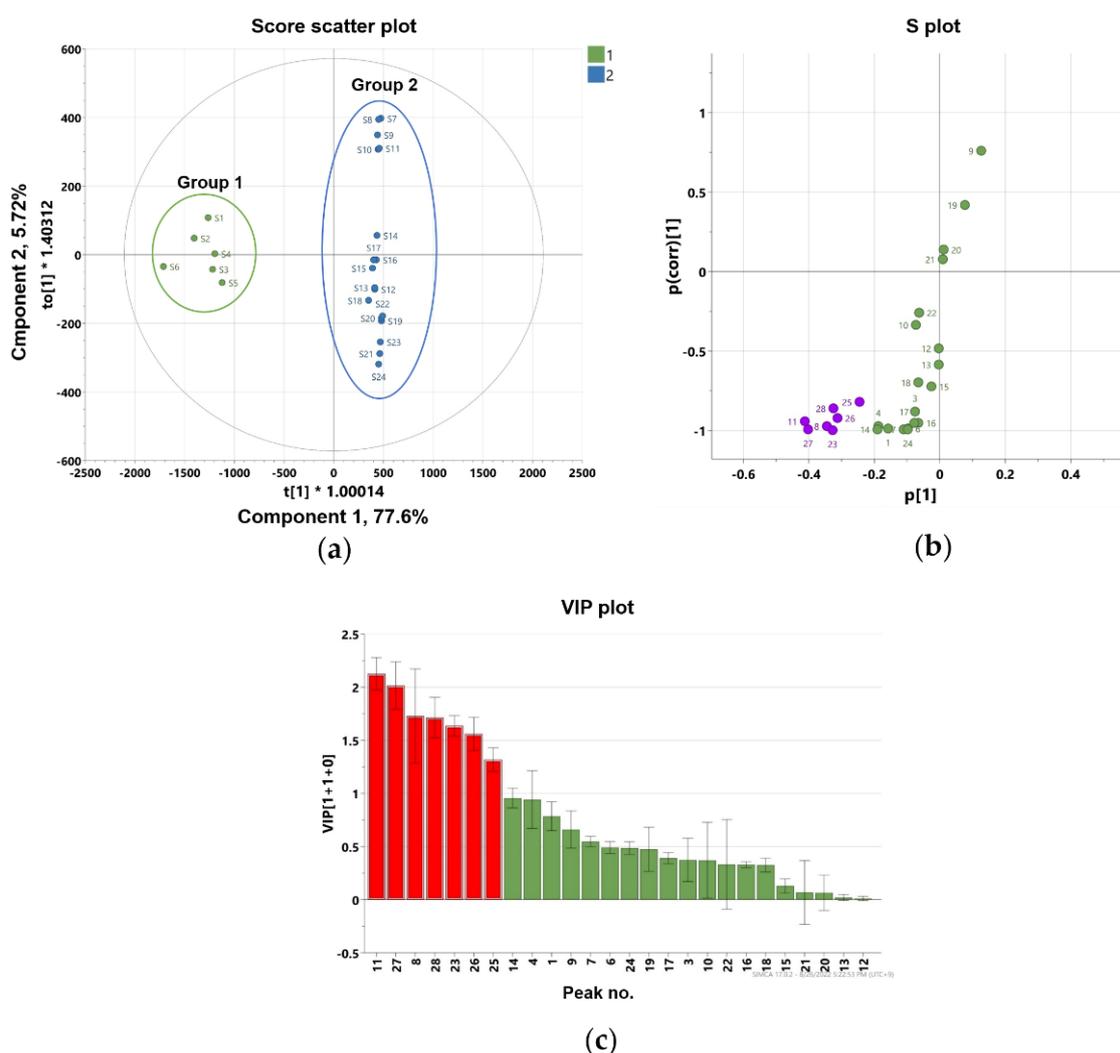

**Figure 3.** Effects of the methanol extract of four different parts of *Peucedanum japonicum* (50 µg/mL) (a) on Aldo-keto reductase (AKR)1C1 activity, (b) cell viability, and (c) optical density (OD) over time, in A549 human non-small-cell lung cancer cells. Data are presented as means  $\pm$  SD of three independent experiments. \*  $p < 0.05$  vs. control.

To further identify marker compounds responsible for the potency of flower samples, OPLS-DA with a VIP-plot and S-plot were used to compare the groups. Flower samples (S1–S6) were designated as Group 1, while root (S13–S18), leaf (S7–S12), and stem samples (S19–S24) were designated as Group 2. In the OPLS-DA model, flowers versus roots, leaves, and stems were clearly differentiated into two clusters (Figure 5a). The OPLS-DA model had a cumulative R2Y value of 1.00 and a cumulative Q2 value of 0.968. The internal validation of the OPLS-DA model was conducted by a permutation test ( $n = 200$ ). The intercept values of R2 and Q2 in the permutation test were -0.0066 and -0.399, respectively. All permutations to the left of the R2 and Q2 values were less than the original points to the right (Figure S32). These values indicated that the OPLS-DA model for the analysis

was robustly validated and not overfit. Several potential marker compounds capable of distinguishing the two groups were located apart from the center of the corresponding OPLS-DA S-plot (Figure 5b). Seven coumarins, peaks 8, 11, 23, 25–28, were shifted in the same direction as the Group 1 samples on the score scatter plot. The variable importance for the projection plot (VIP-plot, Figure 5c) indicates that these seven coumarins are the primarily responsible markers for discriminating between Group 1 and Group 2 with significant VIP values ( $VIP \geq 1$ ). This indicates that the Group 1 samples contained higher concentrations of these coumarins compared with the Group 2 samples. Therefore, the composition and relative content of key markers that differentiate between flowers and other parts contribute to distinguishing active and inactive plant parts.

**Figure 4.** Principal component analysis (PCA) (a) score plot and (b) loading plot of the metabolome analysis of flower, root, leaf, and stem of *P. japonicum*; (c) bar chart—showing the variable average for the different parts (flower, root, leaf, and stem) of *P. japonicum*.

**Figure 5.** Orthogonal partial least square-discriminant analysis (a) score plot and (b) S-plot exhibit markers for differentiating flower and root, stem, and leaf parts of *P. japonicum* (purple color shows the most deviated variables from the center), (c) the variable importance for the projection plot (VIP-plot) scores of the selected markers (red color shows the variables with VIP values  $\geq 1$ ).

### 3. Materials and Methods

#### 3.1. Plant Materials

*P. japonicum* was grown under constant soil conditions in an experimental field located at 35.5114° N latitude by 126.8312° E longitude at the Advanced Radiation Technology Institute, Korea Atomic Energy Research Institute (Jeongeup-si, Jeollabuk-do 56212, Korea) for two years. This plant was bred and identified by Gileung Lee and Hong-Il Choi, co-authors of the study. The different parts of the *P. japonicum* plant (flowers, roots, leaves, and stems) were collected in October 2021, freeze-dried, and stored at  $-20$  °C in polyethylene plastic bags until further use. The voucher specimens were deposited at the Advanced Radiation Technology Institute, Korea Atomic Energy Research Institute.

#### 3.2. Sample Preparation

Freeze-dried parts of *P. japonicum* (flowers, roots, leaves, and stems) were ground into powder using a mixer. Six samples were prepared from each part and designated as follows: S1–S6 for flower, S13–S18 for root, S7–S12 for leaf, S19–S24 for stem parts. Then, 1 g of each sample was extracted with 20 mL of methanol in an ultrasonic bath for 1 h and then concentrated. The dried extract (10 mg) was dissolved in 1 mL of methanol and

filtered using a 0.20 µm polyvinylidene fluoride filter. The samples were diluted with methanol to a concentration of 500 ppm for further LC–MS analysis. For the evaluation of bioactivity, each dried extract was initially dissolved in dimethyl sulfoxide (DMSO) at a concentration of 50 mg/mL. All extraction and chromatographic solvents used in this study were of analytical grade (J. T. Baker, Phillipsburg, NJ, USA).

### 3.3. UPLC-QToF MS Analysis

A Waters ACQUITY UPLC H-Class system combined with a SYNAPT XS QToF MS (Waters, Milford, MA, USA) was used. Each sample (1 µL) was injected into an ACQUITY UPLC BEH C18 column (100 × 2.1 mm i.d., 1.7 µm) at a flow rate of 0.4 mL/min. The temperature of the column oven was maintained at 40 °C. The mobile phase was composed of 0.1% formic acid in water (*v/v*; solvent A) and 0.1% formic acid in acetonitrile (*v/v*; solvent B). Gradient elution was carried out as follows: 0–2.0 min, 30% B; 2.0–6.0 min, 30–45% B; 6.0–11.0 min, 45–50% B; 11.0–14.0 min, 50–55% B; 14.0–18.0 min, 55% B; 18.0–21.0 min, 55–60% B; 21.0–25.0 min, 60–100% B; 25.0–27.0 min, 100% B; 27.0–27.1 min, 100–30% B; and 27.1–30.0 min, 30% B. The mass spectrometer was operated in positive ion mode using the following parameters: source temperature, 110 °C; desolvation temperature, 350 °C; capillary voltage, 2.5 kV; cone voltage, 50 V; cone gas flow: 50 L/h; flow rate of desolvation gas (N<sub>2</sub>), 800 L/h; mass scan range, 100–1200 Da; scan time, 0.5 s. Leucine-enkephalin was used for the lock mass ( $[M + H]^+$  *m/z* 556.2771). Full scan data, MS/MS spectra, accurate mass, and elemental composition were calculated using UNIFI software (version 3.03, Umetrics, Umeå, Sweden).

### 3.4. Aldo-Keto Reductases Activity Assay

The AKR1C1 activity of the extracts was measured using the EZDetect™ Aldo-keto Reductase Activity Assay Kit (Colorimetric) (BioVision Inc., Waltham, MA, USA), based on the manufacturer's instructions. In this assay, AKR uses a general substrate to convert nicotinamide-adenine dinucleotide phosphate (NADP<sup>+</sup>) to dihydronicotinamide-adenine dinucleotide phosphate (NADPH). NADPH reacts with the AKR probe and generates a color which is proportional to the activity of AKR in the sample. To determine the effect of the extract on AKR enzyme activity in A549 non-small-cell lung cancer cells (American Type Culture Collection, Rockville, MD, USA), the cells were cultured in a 6-well plate at a density of 5 × 10<sup>5</sup> cells/mL for 24 h. They were subsequently treated with the extracts at a concentration of 50 µg/mL for an additional 24 h. After the incubation period, the cells were harvested according to the Kit manual for measuring AKR1C1 activity. The assay was performed using a single experiment and the samples were evaluated in triplets.

### 3.5. Statistical and Multivariate Analysis

The data set of the measured mass values and intensities (peak area) for each sample was exported to SIMCA 17.0.2 (Umetrics, Umeå, Sweden) and analyzed by multivariate statistical analysis including PCA and orthogonal partial least-squares discriminant analysis (OPLS-DA). An S-plot was used to identify the potential marker compounds that are responsible for the differentiation of the flower part from the root, leaf, and stem parts. Statistical analysis of the biological assay was performed to identify significant differences between the control and test groups (unpaired *t*-test) using GraphPad Prism9 software (GraphPad Prism version 9.0.0 (121) for Mac, San Diego, CA, USA).

## 4. Conclusions

A comparative study was done to identify coumarin composition and AKR1C1 inhibitory activities in different parts of *P. japonicum*. UPLC-QToF MS analysis was used to identify 28 compounds, including three coumarins which have not been reported in the genus *Peucedanum*. Among the methanol extracts of different parts of *P. japonicum*, the flower extract exhibited AKR1C1 activity inhibition in A549 cells at a concentration of 50 µg/mL without cytotoxicity. PCA results showed that the metabolites discrimi-

nate among the flower, leaf, stem, and root samples of *P. japonicum* and the OPLS-DA results revealed the responsible markers for discriminating between the active flower extract and the other three inactive parts. These markers were tentatively identified as isoimperatorin (peak 8), 3'-O-acetyl-4'-O-(2-methyl butanoate)khellactone (or 3'-O-acetyl-4'-O-isovalerylkhellactone; peak 11), 3'-O-(2-methyl butyryl)-4'-O-isobutyrylkhellactone (or 3'-O-isovaleryl-4'-O-isobutyrylkhellactone; peak 23), and compounds having a khellactone structure, in which four substituents, angeloate, senecioate, 2-methyl butyrate, and isovalerate groups, were frequently substituted at C-3 and C-4 (peaks 25–28). Therefore, these markers have the potential to have the ability to inhibit AKR1C1 activity, however further study involving the isolation of these compounds, the determination of their structures and stereochemistry, and the evaluation of their AKR1C1 activity inhibitory effects is required.
