## **S1. Characterization methods and details analysis**

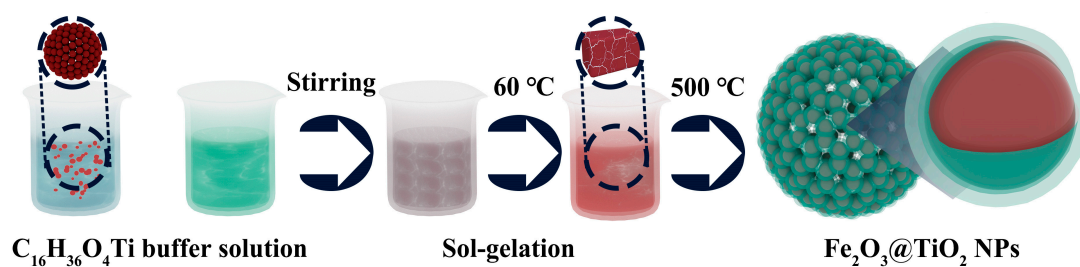

### **S1.1. Materials characterization**

Transmission electron microscopy (TEM, Tecnai 20U-Twin microscope) is used to examine the morphology. X-ray diffraction (XRD, X'pert Pro MPD) patterns are measured on a diffractometer with Cu-K $\alpha$  radiation ( $\lambda = 0.15443$  nm). Raman spectra are collected with 532 nm photons from an Ar<sup>+</sup> laser. X-ray photoelectron spectroscopy (XPS) is inspected on the Thermo ESCALAB 250.3.

### **S1.2. Device assembly measurements**

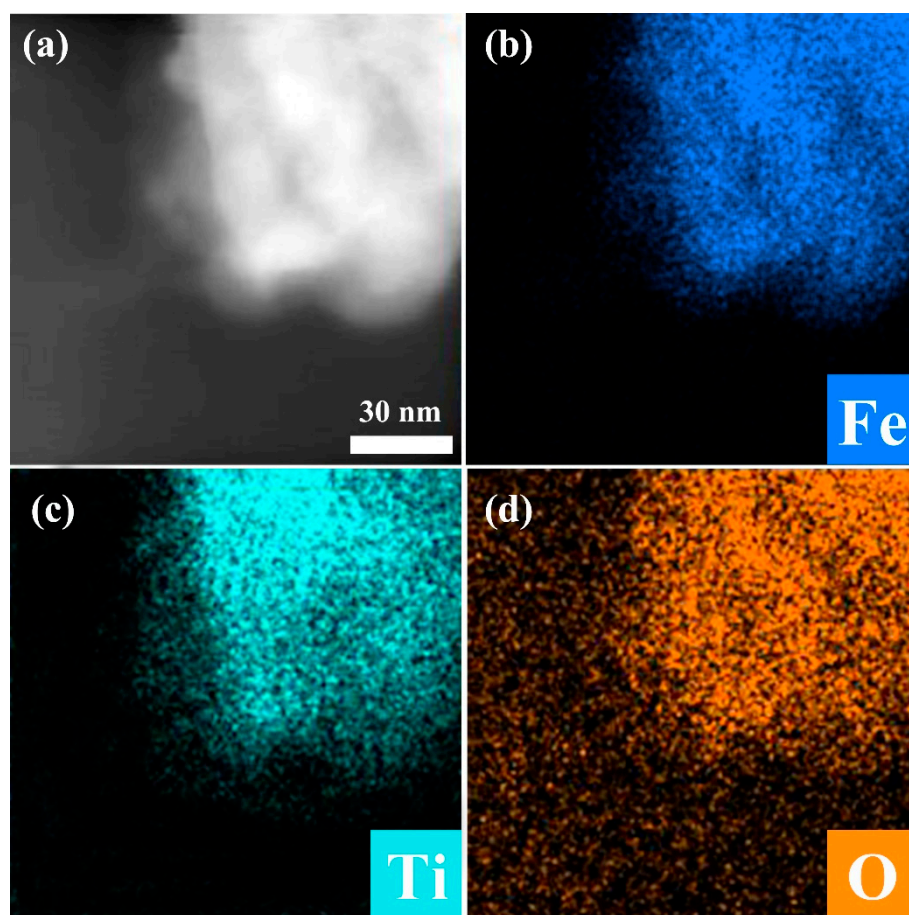

The CR2016-type coin cells are assembled in an argon-filled glove box. Li metal is used as the counter and reference electrode. The positive and negative electrodes are electronically separated by a polypropylene film (Celgard 2320) saturated with electrolytes. The electrolyte solution is LiPF<sub>6</sub> (1 M) in ethylene carbonate/dimethyl carbonate/diethyl carbonate (1:1:1 vol %). The cycling and rate performances are recorded on a NEWARE battery measurement system, and cyclic voltammetry (CV) is performed using a CHI660D electrochemical workstation (Shanghai CH Instruments Co., China). Electrochemical impedance spectroscopy (EIS) measurements are also carried out on the CHI660D electrochemical workstation.

## S2. Results and discussion

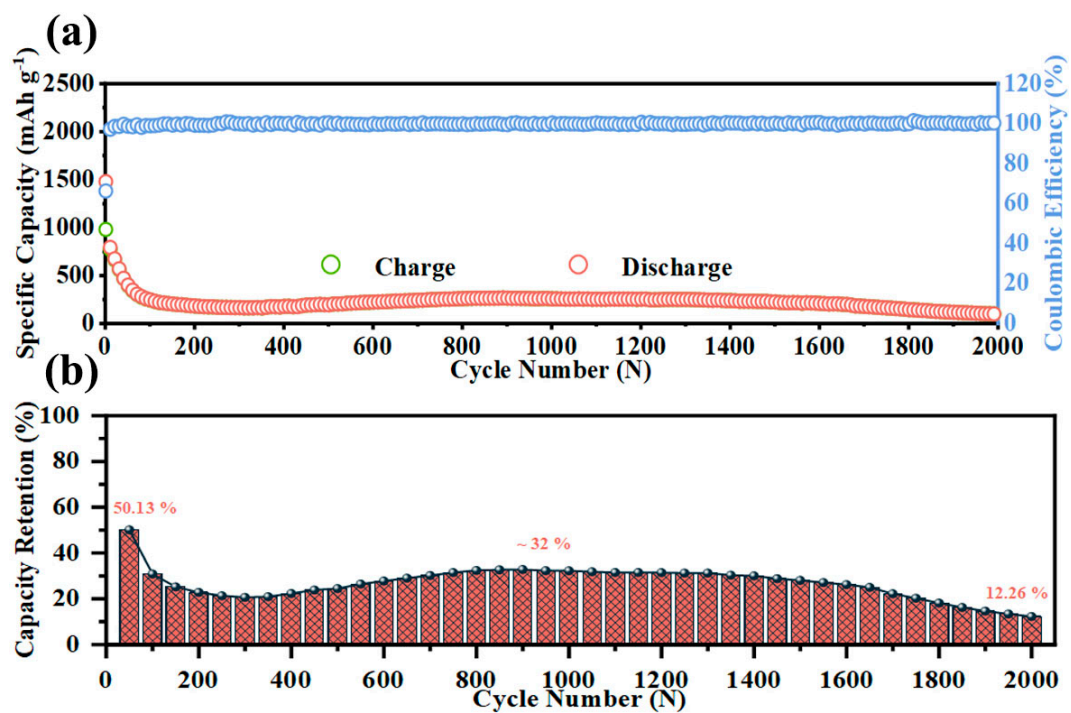

**Figure S1.** Preparation of  $\text{Fe}_2\text{O}_3@\text{TiO}_2$  heterostructure.

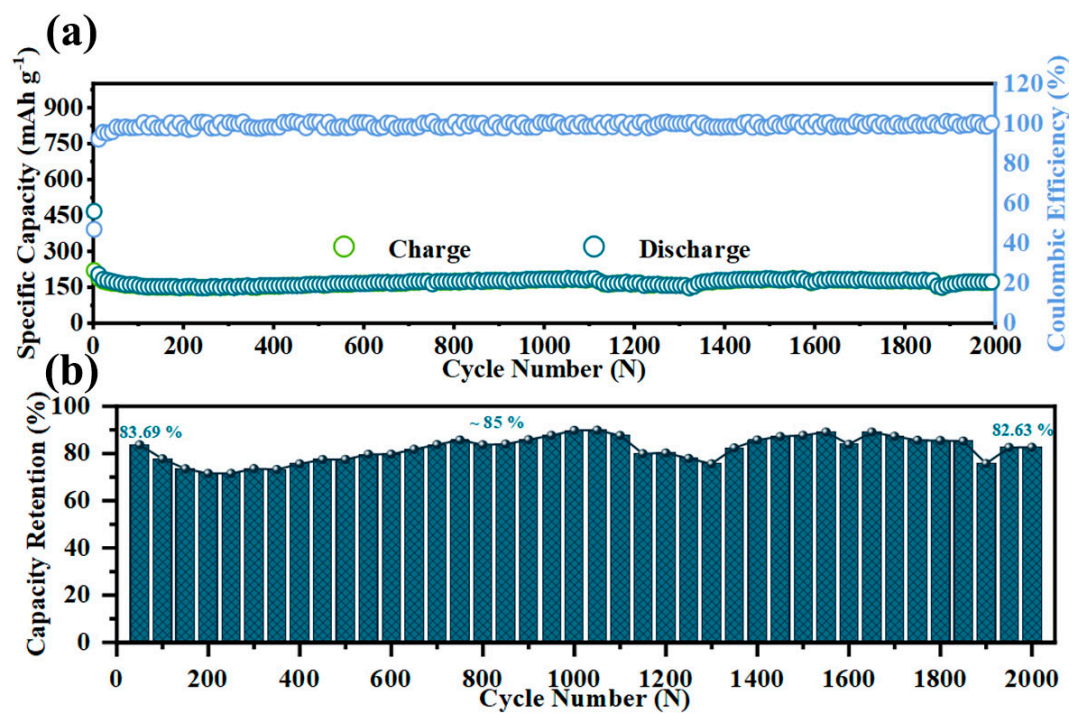

$\text{Fe}_2\text{O}_3@\text{TiO}_2$  preparation is divided into three steps. As shown in Figure S1,  $\text{Fe}_2\text{O}_3$  particles are prepared by hydrothermal method. The specific scheme is to dissolve 1 g  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  into 30 ml deionized water, and stirring continuously. Then 0.5 g polyvinylpyrrolidone (PVP) is added into the solution, continuously stirring. The solution is transferred into a polytetrafluoroethylene lining and assembled into a high-pressure reactor.  $\text{Fe}_2\text{O}_3$  particles are obtained by holding at 200 °C for 600 min. The second step is the sol-gel process. Firstly, the buffer solution is prepared, and the 20 ml  $\text{C}_2\text{H}_6\text{O}$  is mixed with 2 ml  $\text{CH}_3\text{COOH}$ . After evenly mixing, 5 ml of  $\text{C}_{16}\text{H}_{36}\text{O}_4\text{Ti}$  is slowly added and continuously stirred. The pre-prepared  $\text{Fe}_2\text{O}_3$  particles are ultrasonically dispersed into 3 ml deionized water, and 10 ml anhydrous ethanol is added to stir well, then the pH value is adjusted with HCl to 4, referred to as dispersion solution 1. Add dispersion solution 1 to the buffer solution slowly, stirring continuously until a gel forms. The gel is aged for 24 h and then put into a vacuum drying box at 60 °C for drying. The powder obtained after drying is fully ground with a mortar. Then it was put into a tube furnace and heated at a heating rate of 10 °C  $\text{min}^{-1}$  to 500 °C under argon atmosphere for 30 min. After natural cooling, reddish-brown powder is prepared as  $\text{Fe}_2\text{O}_3@\text{TiO}_2$ .
