Section S1. Estimation of isosteric heats of gas adsorption.

A virial-type Equation (S1) comprising the temperature independent parameters a_i and b_i was employed to calculate the enthalpies of adsorption for CO₂ (at 273 and 298 K).

$$\ln P = \ln N + 1/T \sum_{i=0}^m a_i N^i + \sum_{i=0}^n b_i N^i \quad (\text{S1})$$

P : pressure, N : the amount adsorbed (or uptake), T : temperature, a_i and b_i : virial coefficients, and m, n : the number of coefficients required to adequately describe the isotherms (m and n were gradually increased until the contribution of the extra added a and b coefficients was deemed statistically insignificant towards the overall fitting, and the average value of the squared deviations from the experimental values was minimized). The values of the virial coefficients (a_0 to a_m) were then used to calculate the enthalpies heats of adsorption using the following expression.

$$Q_{st} = -R \sum_{i=0}^m a_i N^i \quad (\text{S2})$$

Q_{st} is the coverage-dependent isosteric heat of adsorption and R is the universal gas constant. The heat of CO₂ sorption for (S1) and (S2) in this manuscript is determined by using the excess sorption data in the pressure range from 0–1 atm (273 and 298 K), which is fitted by the virial-equation very well.
