Estimates of (α , γ , δ)	2
Estimates of confidence interval for RR _{IER}	2
Table S1	3
Figure S1	4
Figure S2	5
Table S2	5
Reference	12

Estimates of (α , γ , δ): A set of RR estimates $\{\hat{r}_1^{(s)}, \dots, \hat{r}_{Ks}^{(s)}, s = 1, \dots, S\}$ and corresponding confidence intervals based on PM_{2.5} concentrations $\{z_1^{(s)}, \dots, z_{Ks}^{(s)}, s = 1, \dots, S\}$ can be obtained from previous research, where S means different types of PM_{2.5} sources and Ks is the number of RR estimates available from for source type S. In order to estimate α , δ and γ , flowing steps are needed: First, determine the logarithm of the relative risk estimates $\{\hat{r}_1^{(s)}, \dots, \hat{r}_{Ks}^{(s)}, s = 1, \dots, S\}$ denoted by $\{\hat{\gamma}_1^{(s)}, \dots, \hat{\gamma}_{Ks}^{(s)}, s = 1, \dots, S\}$ and then denote the standard error of $\{\hat{\gamma}_1^{(s)}, \dots, \hat{\gamma}_{Ks}^{(s)}, s = 1, \dots, S\}$ by $\{\hat{v}_1^{(s)}, \dots, \hat{v}_{Ks}^{(s)}, s = 1, \dots, S\}$. After that, generate 1000 realizations of the log-relative risks assuming a normal distribution with mean $\{\hat{\gamma}_1^{(s)}, \dots, \hat{\gamma}_{Ks}^{(s)}, s = 1, \dots, S\}$ and standard deviation $\{\hat{v}_1^{(s)}, \dots, \hat{v}_{Ks}^{(s)}, s = 1, \dots, S\}$ and take their exponents. One thousand estimates of (α , γ , δ) could be obtained for each set of simulated RRs. The estimation routine did not converge in a small percentage of cases (< 5%) due to a set of simulated RR that were not consistent with the risk model form in our practical processing. Thus we continue to simulate relative risks until 1000 estimates of (α , γ , δ) were obtained [1].

Estimates of confidence interval for RR_{IER}: We simulated 1,000 sets of source type-specific RRs based on their point estimates and CIs and fit the IER model to these simulated values, obtaining 1,000 sets of parameter estimates of (α , γ , δ) and z_{cf} . Using these parameters, we then generated

1,000 IER values over the global concentration range. The mean of these 1000 IER values at a specific concentration was used as our central estimate of relative risk, and the 2.5% and 97.5% values among the 1000 IER values were used to form the lower and upper confidence intervals for each disease at each specific concentration [1].

Table S1. Change of PM_{2.5} concentration in provinces from 2015 to 2016.

Province	Average change of PM _{2.5} from 2015 to 2016 per city ($\mu\text{g}/\text{m}^3$) ^a	Number of cities ^b	Cities with increasing PM _{2.5}		Cities with decreasing PM _{2.5}	
			Number	Rate (%)	Number	Rate (%)

^a “+” reflects an increase in PM_{2.5} from 2015 to 2016, and “−” reflects a decrease in PM_{2.5} from 2015 to 2016.

^b Cities without records of PM_{2.5} are not included.

^c Shanghai, Beijing, Chongqing and Tianjin are municipalities of China.

Figure S1. Proportion distributions of hourly PM_{2.5} concentrations (in the range of ≤10 µg/m³ (a), 10–15 µg/m³ (b), 15–25 µg/m³ (c), 25–35 µg/m³ (d), > 35 µg/m³ (e)) in 336 cities.

Figure S2. Diurnal variation of PM_{2.5} concentration in four seasons over 2015 and 2016.

Table S2. Changes in deaths caused by fluctuations of PM_{2.5} concentrations from 2015 to 2016 in 336 Chinese cities.

Province	City	PM _{2.5} (µg/m ³)		Change of death number from 2015 to 2016
