

Annex 3. Simulations in MAT ratio (y-axis) following $\pm 10\%$ and $\pm 25\%$ variations in Tmax (x-axis) in a series of oral targeted anticancer drugs. The calculated MAT ratio from the respective induction and inhibition DDI studies correspond to 0 %.

MAT ratio outside the 0.77-1.30 interval, and remaining outside this interval following simulation variations in Tmax ($\pm 10\%$) are considered as relevant marker of a variation in the absorption rate. The methodology of calculation is described in details in the material and method section.
