

Supplementary data

Supplementary figures

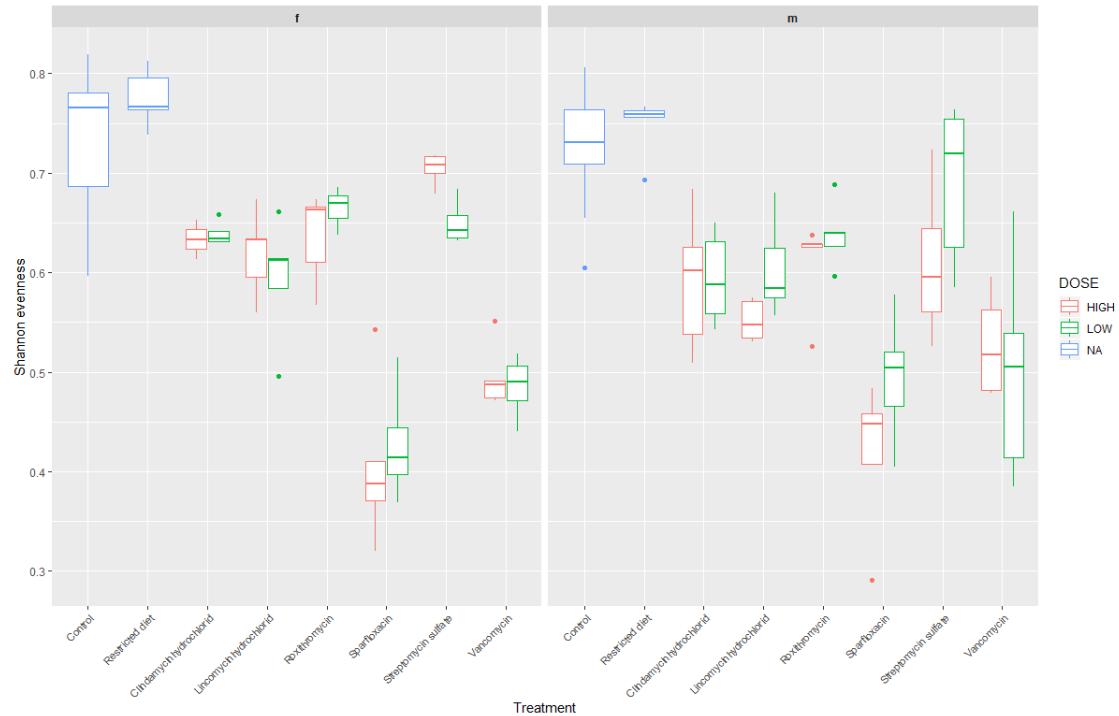

Figure S1: Shannon Evenness for all the treatments including both sexes and dose groups. Ranges from 0 to 1 where 0 means the bacterial diversity is uneven whereas 1 means the evenness in the different bacterial taxa present is higher. (dots are individual samples, solid lines between the boxes are medians)

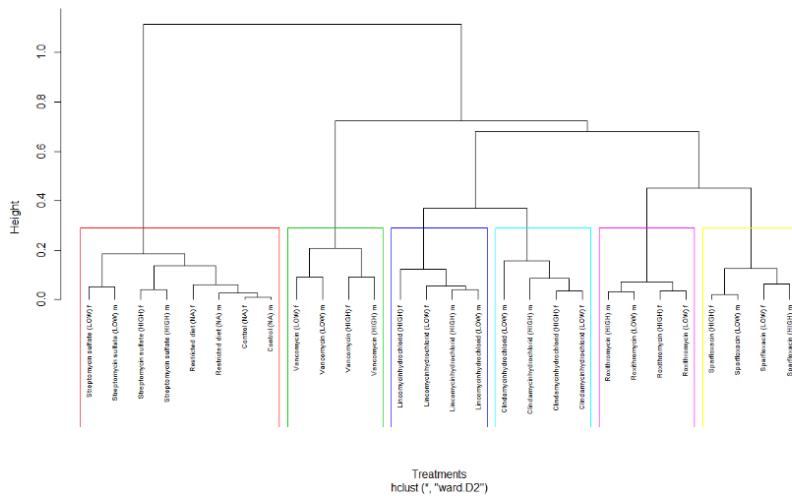

Figure S2: Hierarchical clustering (HCA) analysis of 16S gene sequencing data. Dendrogram showing hierarchical clustering of 16S rDNA gene sequencing of different treatments, dose groups and sex. Euclidean distance was used, and different treatments are depicted, and different colors and dotted boxes show different clusters

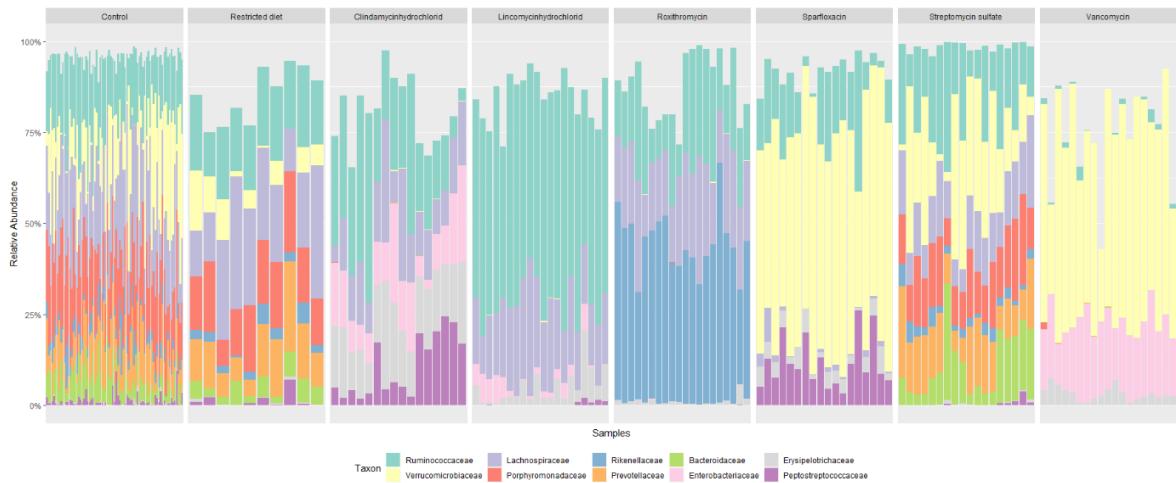

Figure S3: Relative abundance analysis of bacterial families for individual animals. Dose groups and sexes showed very marginal differences hence they were not separated. The most abundant families have higher contributions in the bars. The bars did not add up to 100% as the unclassified bacterial families with no taxonomic assignments were removed. Ten different bacterial families have been observed to be present relatively abundantly in the controls, restricted diet fed and different antibiotic treatments.

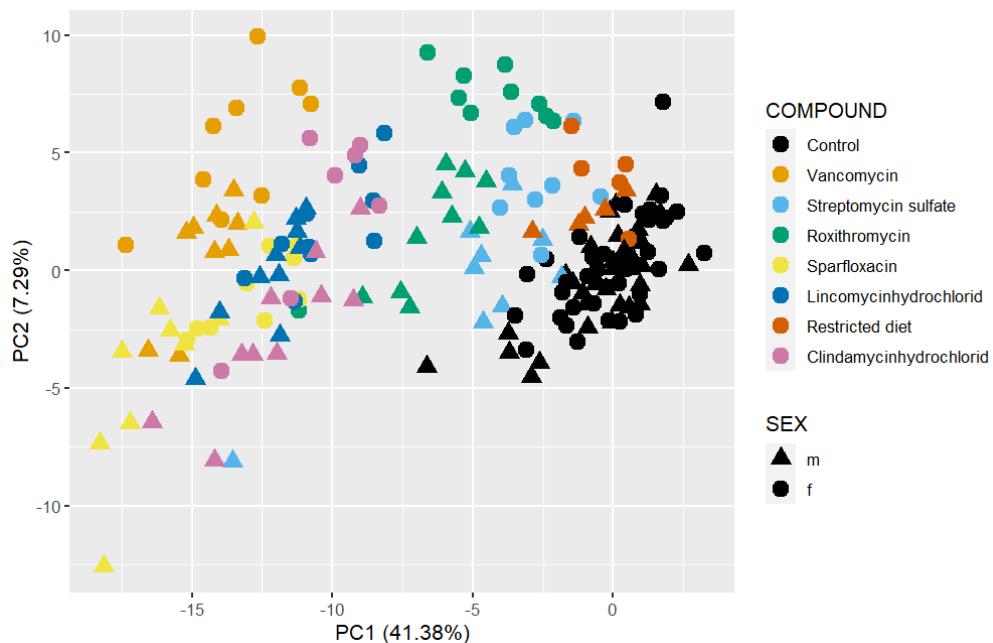

Figure S4: Principle Component Analysis (PCA) of feces metabolites from different treatments. Different colors depict different treatment groups where triangle shaped dots refer to male animals and circles refer to females.

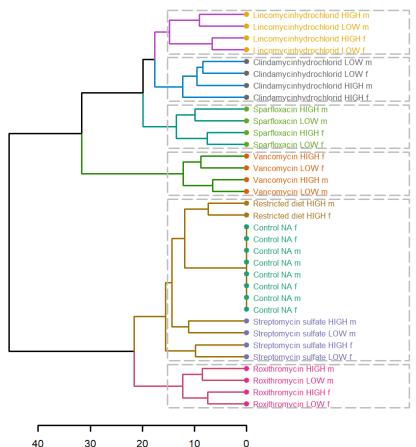

Figure S5: Dendrogram showing hierarchical clustering of cecum metabolites of different treatments, dose groups and sex. Euclidean distance was used, and different treatments are depicted, and different colors and dotted boxes show different clusters.

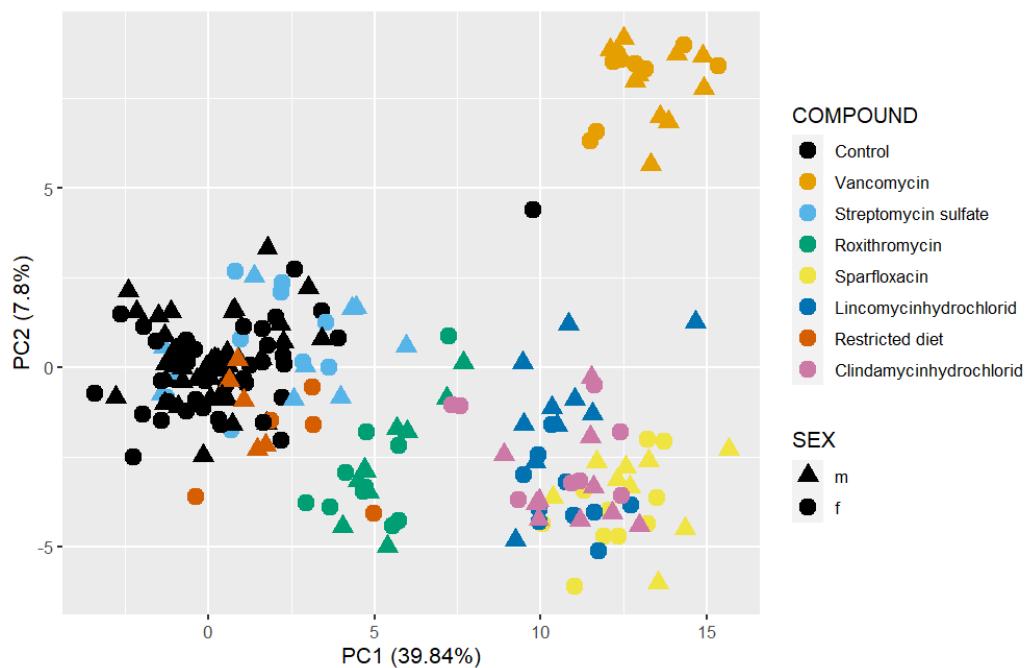

Figure S6: Principle Component Analysis (PCA) of cecum metabolites from different treatments. Different colors depict different treatment groups where triangle shaped dots refer to male animals and circles refer to females.

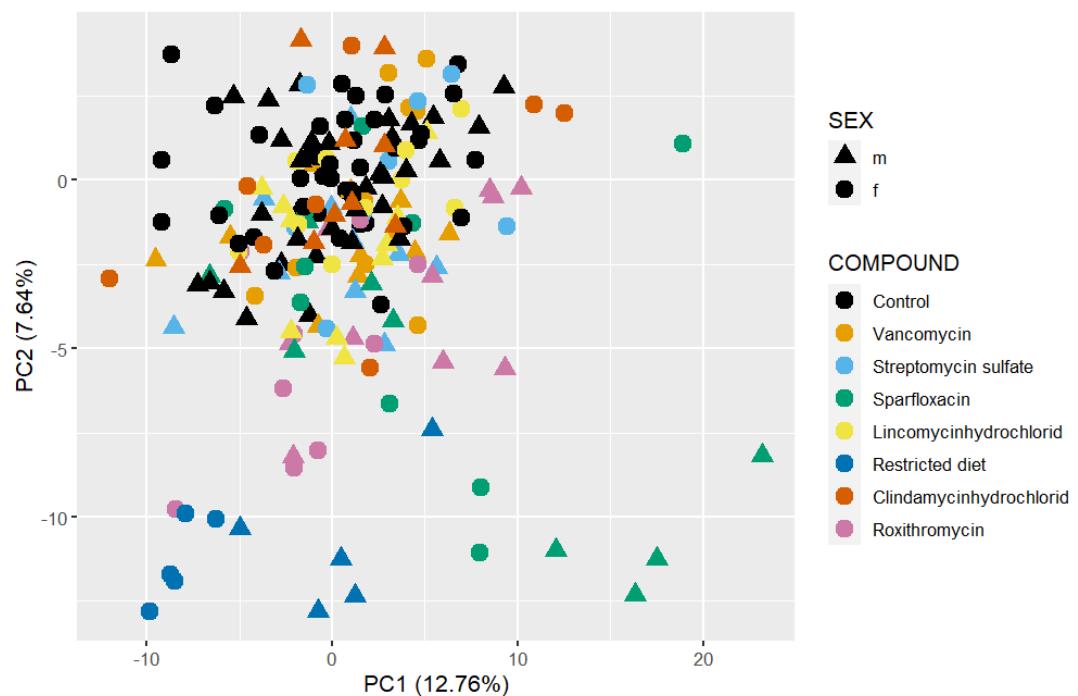

Figure S7: Principle Component Analysis (PCA) of plasma metabolites from different treatments. Different colors depict different treatment groups where triangle shaped dots refer to male animals and circles refer to females.

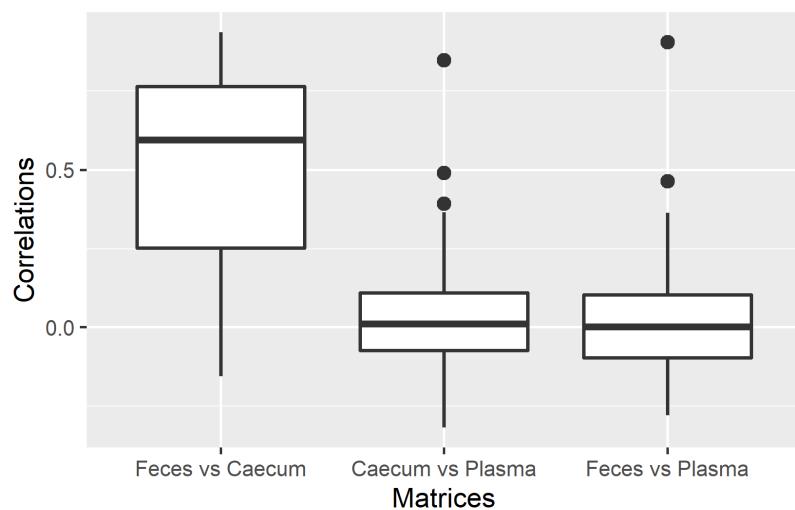

Figure S8: Boxplots comparing between different metabolome matrices. The value refers to correlation coefficient values and the dots represent outliers or metabolites that do not fall in the range of other metabolites.

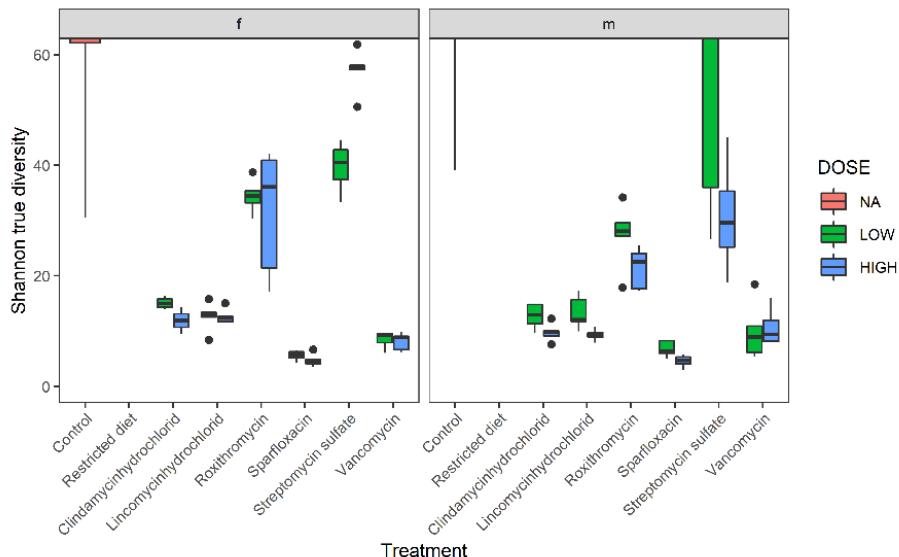

Figure S9: Shannon true diversity analysis of six antibiotic treatments focused for both male and female Wistar rats. Boxplot on the left show the diversity analysis for females (f) and right for the males (m). The colors show different dose groups, where blue box refers to high dose and green refers to low dose groups. The x-axis shows the different treatment groups and y-axis shows Shannon diversity value; whiskers denote standard deviations, solid lines within the boxes indicate the group median and dots lying outside the boxes are outliers. On removing control and restricted diet groups and focusing on the antibiotics only, we zoom in the focus to the fact that high dose groups have majorly lower alpha diversity. Minor differences could be observed but we cannot essentially say if they are statistically significant. Streptomycin sulfate group show higher variability in both the sexes compared to others, this could be mainly due to lack of influence of this antibiotic on the gut bacterial composition.

Supplementary tables

Table S1: Relative changes in body weight and food consumption of male and female Crl:Wi(Han) rats ($N = 5$ per group) dosed for 28 days compared to the diet controls. Data were collected on study days 6, 13 and 27. Treated animals did not present any significant changes ($p < 0.05$) in body weight compared to the control groups ($N = 10$ per group).

Antibiotic	Day	Body weight		Food consumption	
		m	f	m	f
Clindamycin	6	0,97	0,99	1,30	0,80
	13	0,95	0,98	1,12	1,19
	27	0,94	1,00	0,99	1,16
Lincomycin	6	1,00	0,99	1,00	0,99

Table S16: The table below shows DESeq2 analysis results from the low dose (LD) groups of all the treatments. The dots in the scatter plot indicate individual ASVs belonging to respective phyla/families. Color coding of the dots is based on the phyla level. The dots indicate positive or negative relative fold changes of specific bacterial ASV in a treatment group with respect to the control group.

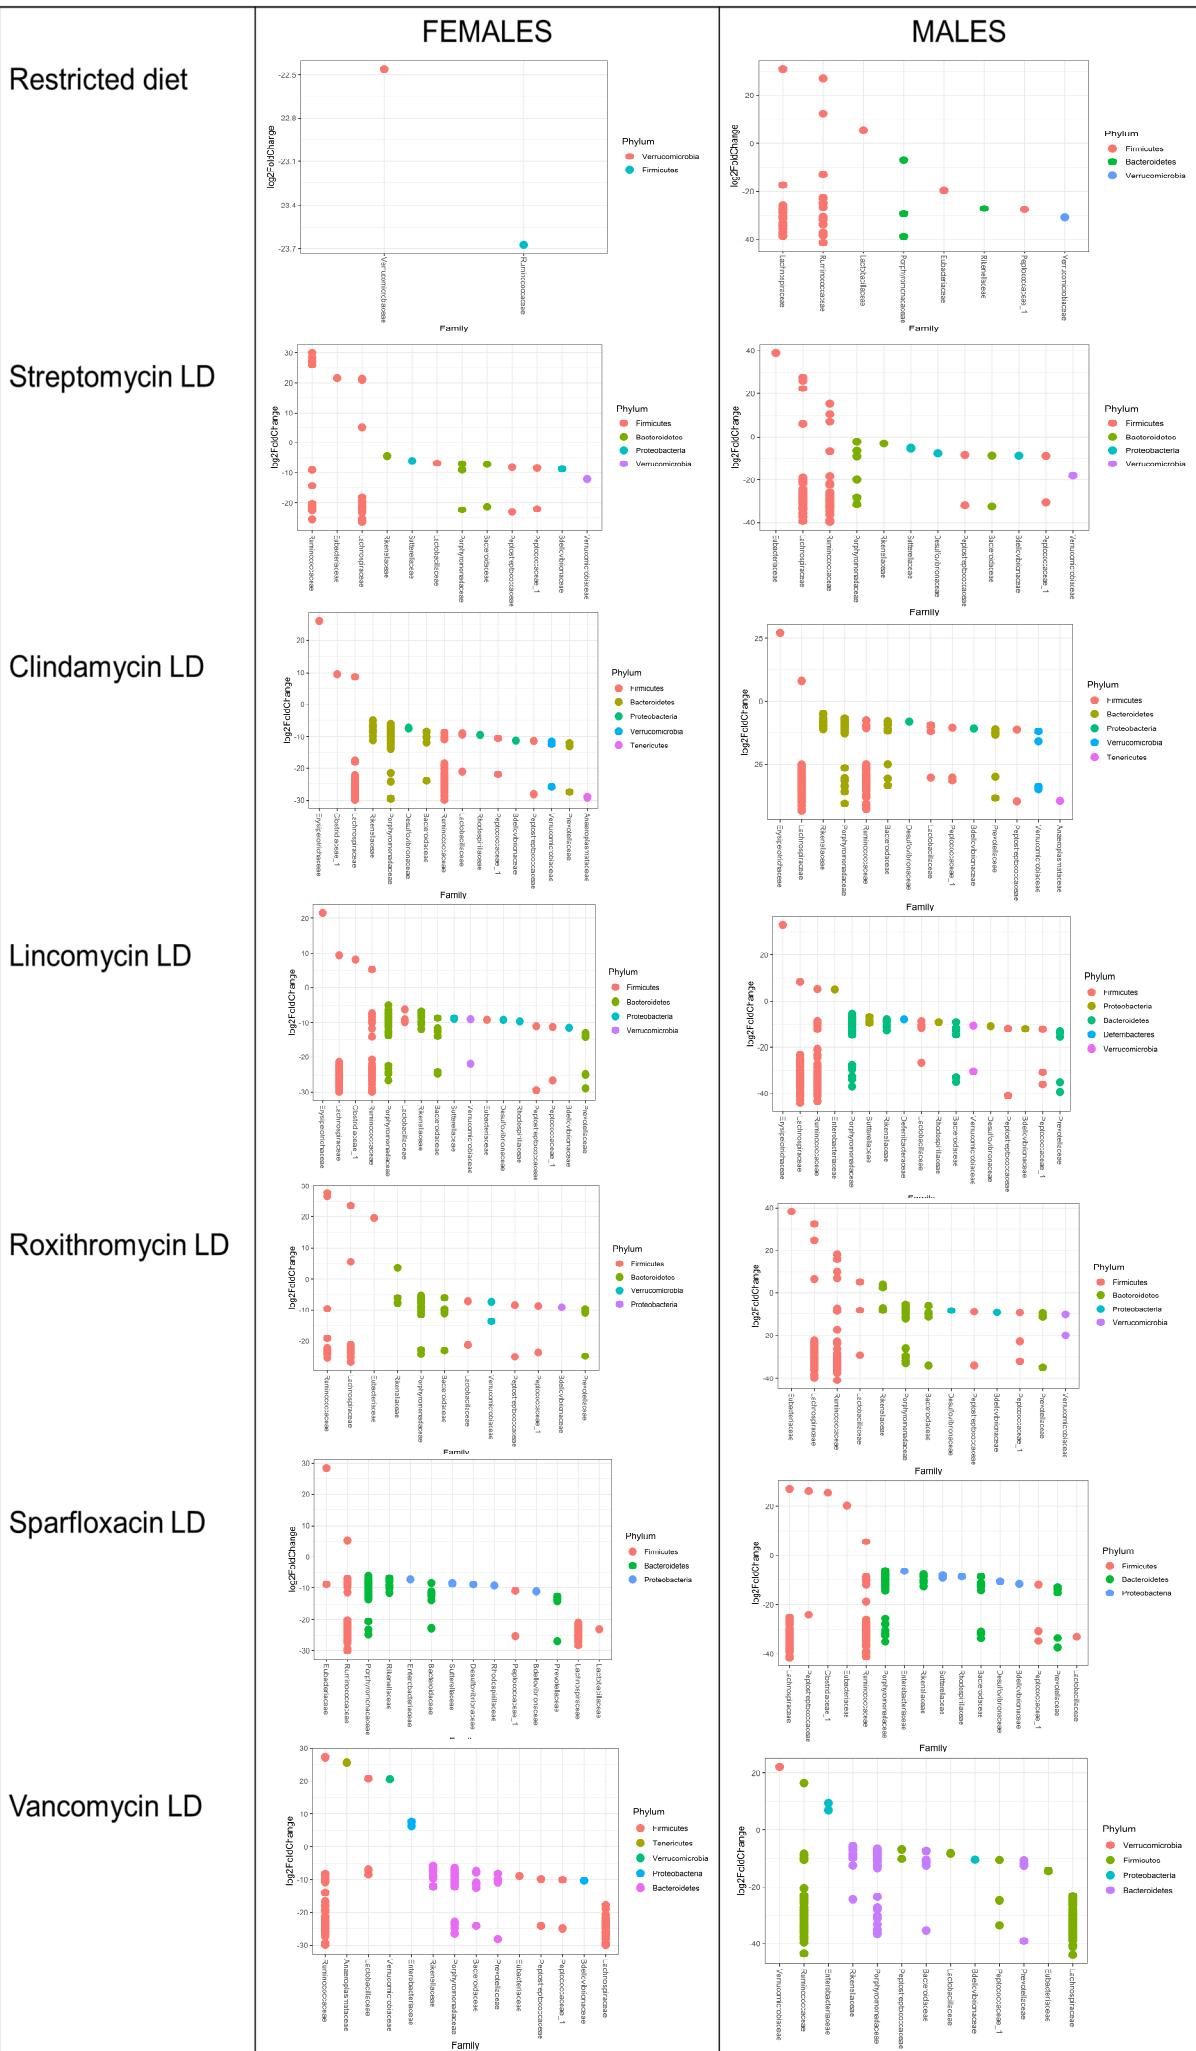

Table S17: Fold changes of different bile acid levels going up (red colored boxes) and down (blue colored boxes) in the feces and plasma matrices of male and female Wistar rats of Lincomycin hydrochloride treatment (p value depends on the shade of the colors, the darkest red is p value<0.01; medium red is p value<0.05 and the lightest shade of red is p value<0.10 and similarly for blue coloring). F represents females, M represents males, 7d, 14d and 28d denote blood sampling time points days 7, 14 and 28 respectively.

METABOLITE NAME	ANALYTE NAME	FECES		PLASMA
