

1. Supplementary methods

1.1. Computation of MET minutes/week

First item of PAQ-C was itself composed by questions about 21 moderate-intensive activities and minutes spent on them.

From Compendium of Physical Activity

(<https://sites.google.com/site/compendiumofphysicalactivities/home>) [1] a

MET value for each activity has been assigned and multiplied for the time (min) children took part on them, obtaining a MET-minutes/week value. [2].

1.2. Extrapolation of dietary data from FFQ

Dietary data have been converted into energy intake (kcal/die) using as references two Italian food composition tables: the one proposed by “Consiglio per la ricerca in agricoltura e l’analisi dell’economia agraria, CREA” (http://nut.entecra.it/646/tabelle_di_composizione_degli_alimenti.html) and the one provided by “Food Composition Database for Epidemiological Studies in Italy” by Gagnarella P, Salvini S Parpinel M. (Version 1.2015 Website <http://www.bda-ieo.it/>). Since FFQ didn’t provide information about portion size we used standard size proposed by Italian Society of Human Nutrition [(SINU), S.I.d.N.U. *Revisione dei Livelli di Assunzione di Riferimento di Nutrienti ed Energia per la Popolazione Italiana (Larn)*. Available online: http://www.sinu.it/html/pag/tabelle_larn_2014_rev.asp] [3].

Food usually consumed as meal have been used: cereals and tubers, dairy products, legumes, fish, vegetables, fresh and dried fruit, meat, FFQ category of fast food, sweets, eggs. PCA is a multivariate technique used to represent a set of inter-correlated quantitative dependent variables into a set of new orthogonal variables called “principal components” [4]. In this case PCs are represented by pattern of food groups consumption that explain the maximum amount of variance [5]. The result of PCA is a factor loading matrix from which the components are derived and a factor score for each individual derived by summing the individual intakes of the food item

weighed by standardized coefficient for each pattern. These scores, one for each pattern, are used in either correlation or regression analysis to examine relationships between various eating patterns and the outcome of interest [6]. Principal Component Analysis (PCA) has been performed using a correlation matrix with varimax rotation. Only eigenvalues greater than 1 has been retained, and only loading scores $>|200|$ has been considered contributing to the pattern.

2. Supplementary tables

Suppl. Table 1. Difference in food intake and physical activity between overweight (BMI $> 85^{\circ}$ percentile for age) or obese (BMI $> 95^{\circ}$ percentile for age) and normal weight.

	Overweight or Obese n=103	Normal Weight n=197	
	<i>mean$\pm$SD</i>	<i>mean$\pm$SD</i>	p-value
Fast Food	1.5 $\pm$ 0.5	1.4 $\pm$ 0.6	n.s.
Cereals and Tubers	1.9 $\pm$ 0.5	2.0 $\pm$ 0.4	n.s.
Vegetables	2.1 $\pm$ 1.0	2.3 $\pm$.9	p<0.05
Fruit	1.6 $\pm$.9	1.5 $\pm$ 0.9	n.s.
Eggs	1.9 $\pm$ 1.0	1.9 $\pm$ 0.9	n.s.
Meat	1.7 $\pm$ 0.6	1.6 $\pm$ 0.6	n.s.
Dairy product	1.9 $\pm$ 0.6	1.9 $\pm$ 0.7	n.s.
Sweets	1.9 $\pm$ 0.7	2.0 $\pm$ 0.7	n.s.
Legumes	1.3 $\pm$ 1.1	1.4 $\pm$ 1.1	n.s.
Fish	0.9 $\pm$ 0.5	1.0 $\pm$.5	n.s.
Nuts	0.8 $\pm$ 1.1	0.9 $\pm$ 1.1	n.s.
Animal-derived fat	0.7 $\pm$ 0.6	0.7 $\pm$ 0.7	n.s.
Evo oil	4.0 $\pm$ 1.1	3.8 $\pm$ 1.4	n.s.
Seed oil	1.5 $\pm$ 1.4	1.2 $\pm$ 1.4	n.s.
Daily energy intake (kcal/die)	2886.14 $\pm$ 1040.2	3076.6 $\pm$ 1243.5	n.s.
PAQ-C score	1.8 $\pm$ 0.5	1.9 $\pm$ 0.5	n.s.
Moderate-vigorous activity (MET-min/wk)	2892.6 $\pm$ 4084.2	3582.0 $\pm$ 3894.8	n.s.
