11 Synthesis of Tris (acetylacetonato) Terbium(III) [Tb(acac)₃•3H₂O]

Tb(acac)₃•3H₂O was prepared according to the literature [1]. At first, TbCl₃•6H₂O (1 mmol) was dissolved completely in ultrapure water (10 mL). which was added the ethanol (1.5mL) dropwise with 3 mmol acac and sodium hydroxide as equal molar mass. The solution was stirred 2.5h at room temperature. The white product was recrystallized from excessive ethanol, followed by filtering and vacuum drying under 70 °C. The white power (64%) was collected over night. ¹H NMR (600 MHz, DMSO) δ 2.14 (s, 1H), 1.45 – 1.30 (m, 1H) (Figure S1).

18 Synthesis of Tb-Containing Metallopolymer (Tb-Poly)

19 Initially, Tb(acac)³•3H₂O was prepared as a precursor though the conventional method. 20 Tb-containing metallopolymer was synthesized by refluxing a mixture of PS-PBPyA and 21 Tb(acac)3•3H2O. The synthesis route is schematically depicted in Figure 1, along with their 22 respective chemical structure. Firstly, PS-PBPyA (5.88 mg, 62.2×10⁻⁴ mmol equal equivalent of bpy) 23 was dissolved in DMF (2.5 mL) in a round bottom flask. Subsequently, Tb(acac)³•3H₂O (1.53 mg) 24 dissolved in ethanol (1 mL) was added to the flask. The mixture was refluxed 3 h under nitrogen. 25 After the solution cooled to room temperature and then precipitated with ethanol. The precipitate 26 was centrifuged 10 min under 8000 r/min and dried over the night. The product was collected 2.74 27 mg (37%) of white powder. ¹H NMR (600 MHz, DMSO) δ 7.20 (s, 1H), 6.66 (s, 1H), 5.32 (d, J = 4.7 Hz, 28 2H), 3.47 (d, J = 50.3 Hz, 2H), 2.89 (s, 1H), 2.73 (s, 1H), 2.03 - 1.85 (m, 7H), 1.45 (s, 2H), 1.05 (s, 29 1H)(Figure S2). The relative quantum yield (φ) of Tb-Poly metallopolymer was determined to be 30 ~0.22 calculated according to literature procedures using DMF solution of Tb(acac)₃ (φ = 0.27) as the 31 reference emitter at room temperature [2].

Figure S4 Time-resolved luminescence of Tb-Poly in DMF (gray dot) and in NPs (green dot) at room temperature ($\lambda_{\text{ex}} = 295$ nm). The data are well fitted with a biexponential function ($\mathbb{R}^2 > 0.999$), $I(t) = A_1 \exp(-t/\tau_r) + A_2 \exp(-t/\tau_{nr})$, where τ_r and τ_{nr} are radiative and nonradiative recombination

46 lifetime, and the average lifetime τ_{av} is calculated by $\tau_{av} = \frac{\sum_{i} A_{i} \tau_{i}^{2}}{\sum_{i} A_{i} \tau_{i}}$. Lifetime τ_{av} is thus determined to be

47 1.183 and 0.94 ms for Tb-Poly in DMF and NPs, respectively.

65 3 Optimization of doping ratio of nanosensors

66 To achieve more proper intensity ratio values towards the obtained nanosensors under 67 different dissolved oxygen conditions, emission spectrum of different doping ratios of Ru-Poly to 68 Tb-Poly were extensively studied. As shown in Figure S6, when the ratio of Ru- to Tb-Poly is 7:3, 69 the emission intensity of Ru-Poly is more close to that of Tb-Poly.

70

71 4 Effect of Temperature

72 Considering the slight effect of temperature to oxygen probe's intensity, the temperature 73 dependence of the emission intensity of Ru-Tb NPs were measured under 300 nm and 460 nm 74excitation and recorded every 5 °C from 25 to 45 °C (Figure S10 a). All intensity profiles correspond 75 to a single-exponential function (Figure S10 b), the 545 nm emission intensity exhibits a strong 76 temperature dependency, which decreases by a substantial 40.3 % on going from 25 to 45 °C while 77 intensity at 610 nm just drops 6.6 %. In the case of the Tb³ ion, the emission intensity decreases with 78 increasing temperature due to thermal activation from the emissive ⁵D₄ level of the Tb³ ion to a 79 nonradiative triplet level. In addition, energy transfer from the acac and bpy ligand to the Tb³ ion is

also likely to be influenced by temperature. If the surrounding temperature is unstable, we could use
the change of emission intendity at 545 nm to infer the variety of temperature, which could be a
reference value to calibrate the emission intensity at 610 nm.
