Contents:

- Figure S1.** Condition of applying voltage for dendritic PEDOT:PSS electrodeposition
- Figure S2.** Voltage pulse interval dependence of conductive polymer wire diameter distribution change
- Figure S3.** The transition from LTP to STP

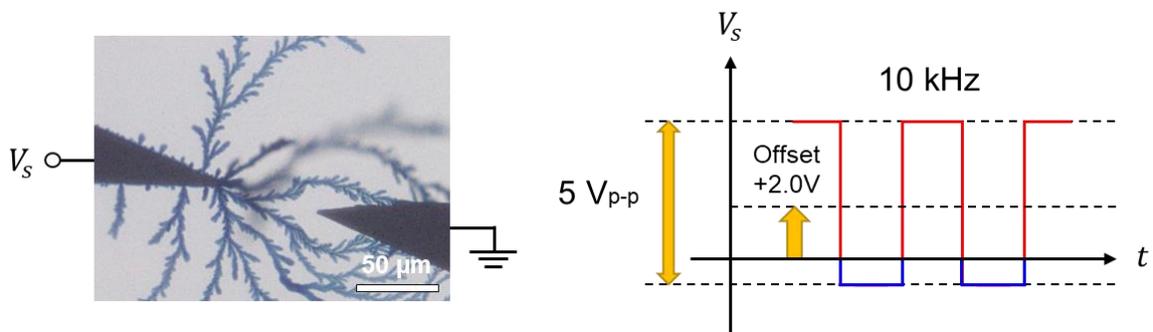

Figure S1. Condition of applying voltage for dendritic PEDOT:PSS electrodeposition. Bipolar square-wave AC voltage (10 kHz, 5 V_{p-p}) with an offset of 2 V was used. By adding an offset, the dendritic PEDOT: PSS grew quickly from one electrode.

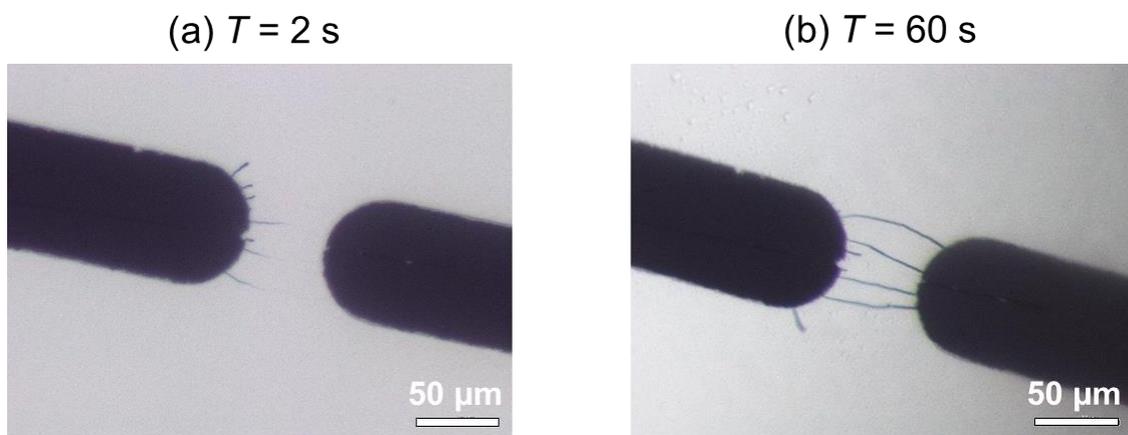

Figure S2. Voltage pulse interval dependence of conductive polymer wire diameter distribution change. Optical microscopic images show the electrode gap crosslinked by conductive polymer wires after voltage pulsing ($V = 2.5V$, $W = 10$ ms) at (a) $T = 2$ s and (b) $T = 60$ s, respectively. When pulses with short intervals were applied, only the anode side of wire became thicker, resulting in an asymmetric wire. On the other hand, pulses with long intervals led to a uniformly thicker wires

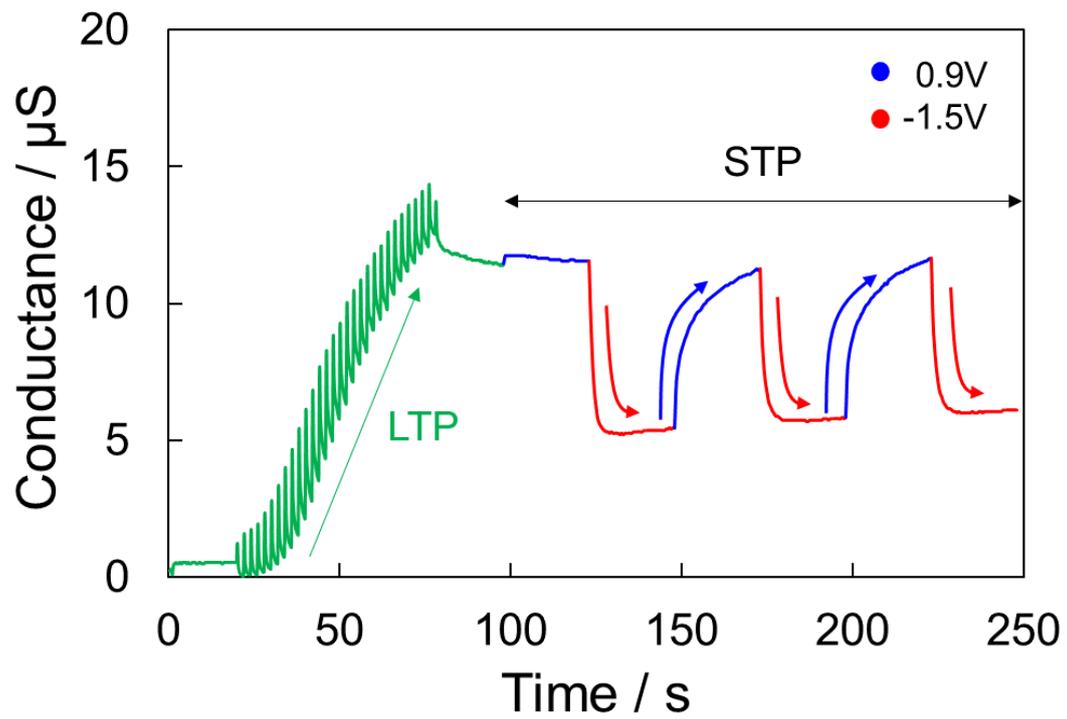

Figure S3. The transition from LTP to STP. After LTP was induced by voltage pulsing ($V = 2.5\text{V}$, $W = 10\text{ ms}$, $T = 2\text{ s}$, 30 times), subsequent STP was induced by voltage pulsing ($V = 0.9$ or -1.5 V , $W = 10\text{ ms}$, $T = 0.5\text{ s}$)
