

## Supplementary Information

**Figure S1.** hiPSC-derived BMECs exposed to LPS secrete only very low levels of cytokines in comparison to the co-culture system. After 0 h and 9 h of LPS (0, 1, 10, 100 ng/mL) exposure in the BMEC (monoculture) system, cell culture supernatant was removed and cytokine concentration quantified with a Luminex® multiplex assay. Data displays the mean change in cytokine concentrations between 0 h and 9 h of LPS exposure. Each graphical symbol shape (square, triangle and circle) represents each set of biological replicates with at least three technical replicates. Mean values  $\pm$  standard deviation of cytokine concentrations for the 0 h and 9 h timepoints are provided in Table S7.

**Table S6.** Cytokine concentrations (pg/mL) at 0 h and 9 h used to calculate the delta mean values provided in Figure 4 (co-culture system exposed to LPS). Each value below represents the mean cytokine concentration from three technical replicates in an experiment (biological replicate). Each row at 0 h and 9 h for each cytokine indicates an experiment with four conditions (thus three cellular experiments were performed) and the supernatants from the same experiment where measured together in the same Luminex® experiment. Thus, each experiment had for each cytokine its own lower limit of detection (LLOD) which was estimated as two standard deviations above background. In case a sample showed for a cytokine a value below the LLOD, this value was replaced by the LLOD in order to still use it for the mean calculation. For each experiment the delta was then calculated between 0 h and 9 h for each cytokine and each condition, respectively.
