1. Comparing the lactating sows and the donor sows

1.1 Housing conditions

The pigs were housed in farming conditions as authorized by the French regulation on animal experimentation for experimentations conducted with an agronomic purpose.
At 106 days of gestation, sows were moved to the farrowing room with natural (windows) and artificial light. They were kept in individual farrowing crates (2 x 2.5 m) equipped with a though and a drinker. The floor of the farrowing pens was made of slatted plastic. The farrowing crates were equipped with 2 infrared heat bulbs for piglets. The ambient temperature was kept at 24 to 25 °C in the lactation rooms with heating and ventilation. Farrowing was induced by an intramuscular injection of prostaglandin F2α (2 mL of Dinolytic, Zoetis, France) on day 114 of gestation. Usual farm practices for newly farrowed piglets were individual identification by tagging, iron injection, tail docking, and castration of male piglets. Cross-fostering, if needed, was performed intra-treatment within 2 days after birth but piglets selected for blood and feces samplings were maintained with her biological mother.

1.2 Ratio of resistant Enterobacteria (Table S1)

Table S1: Counts of tetracycline and sulfamide-resistant Enterobacteria, Ntot number of strains isolated, Ntet and Ptet, number and proportion of strains resistant to tetracylcine, Nsul, number and proportion of strains resistant to sulfonamide. The averages and standard errors are reported as well. It should be noted that the unexpected rise of the proportion of antibiotic-resistant enterobacteria in the donor sows is not due to the use of antibiotics (since no antibiotics were used in the experiment), but could be due to the evolution of the microbiota around parturition [Huang, X.; Gao, J.; Zhao, Y.; He, M.; Ke, S.; Wu, J.; Zhou, Y.; Fu, H.; Yang, H.; Chen, C., et al. Dramatic Remodeling of the Gut Microbiome Around Parturition and Its Relationship With Host Serum Metabolic Changes in Sows. Front Microbiol ***2019***, 10*, 2123, doi:10.3389/fmicb.2019.02123.]*

1.3 ARG abundance in the donor and lactating sows before the experiment

In addition to the ratio of resistant Enterobacteria, we performed a screening based on *blaTEM*, *TetM*, *sul2* and *FlorR* 3 months before the begin of the experiment to ensure that some variability in ARGs profiles was present. The results are indicated in the figure below:

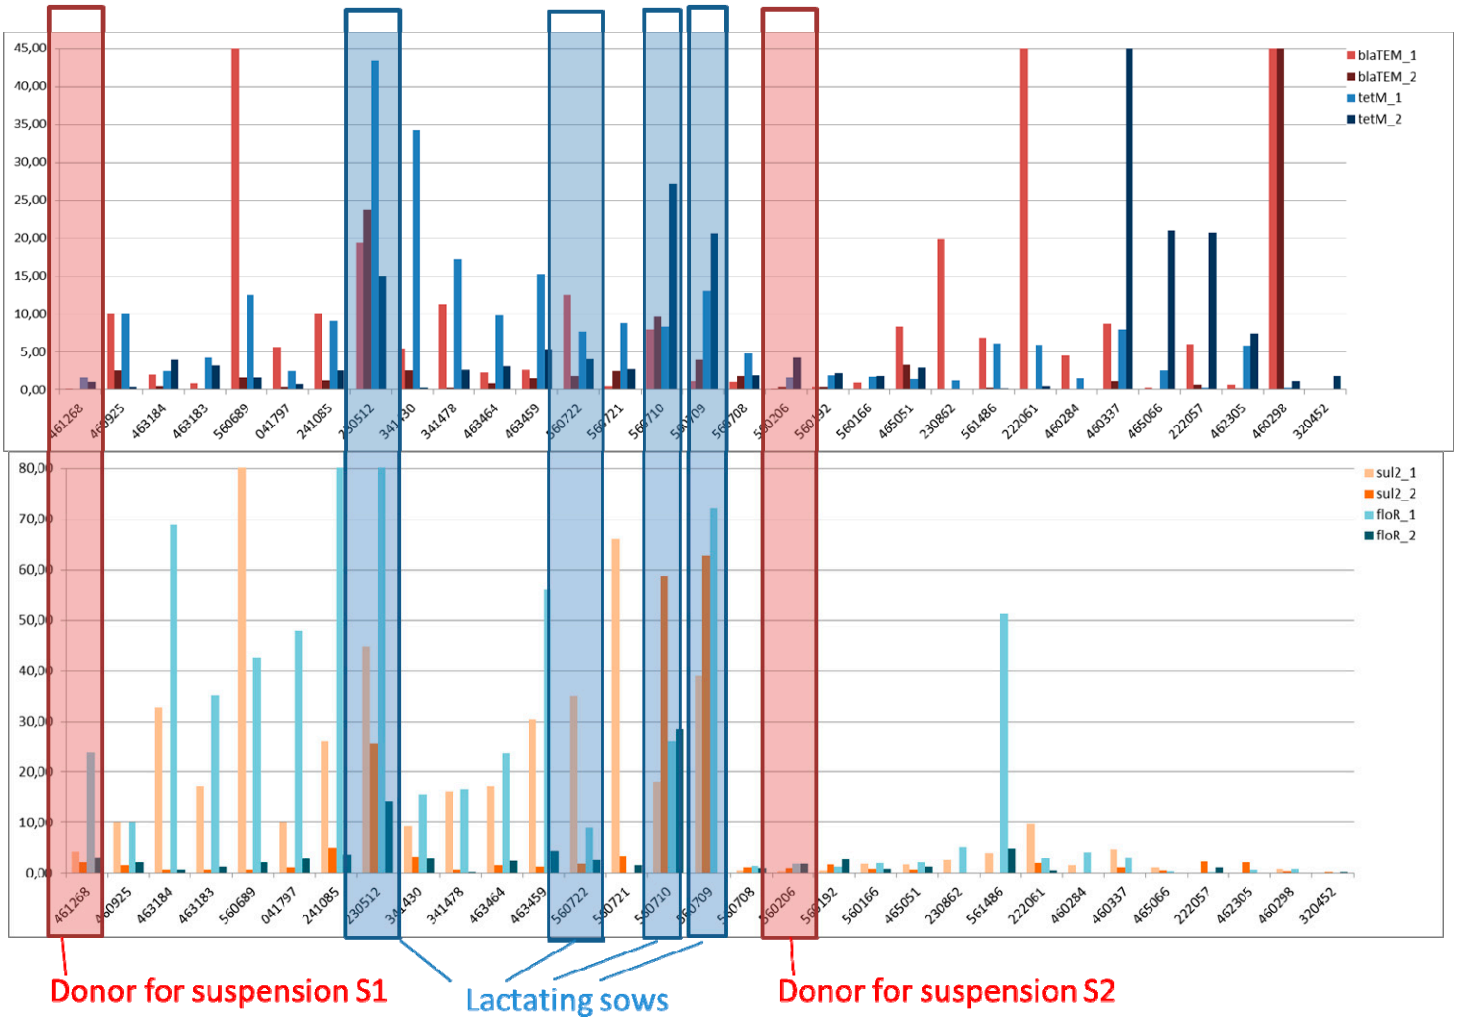

Figure S1: Control of ARG variability in the donor and lactating sows 3 months before the experiment. The ARGs are quantified as described previously.

1.4 ARG abundance in the donor and lactating sows during the experiment (Table S2)

Table S2 : ARG abundances in the 6 samples from the donor sows and in the 12 samples from the lactating sows. The abundances are normalized by the abundance of the 16S rRNA gene. The numbers are not between 0 and 1 because the ARGs were pre-amplified whereas the 16S rRNA genes were not. The measures performed on the day of weaning are in bold. The ARGs aadA, aadA2, lnuB and tetB are highlighted because their uncorrected p-value (according to a wilcoxon test) is lower than 0.05.

			Donor sows (2 sows sampled 3 times)						Lactating sows (4 sows sampled 3 times)

2. Comparing the gavaged and control piglets

2.1 Ratio of resistant Enterobacteria in piglets (Fig S3 and S4)

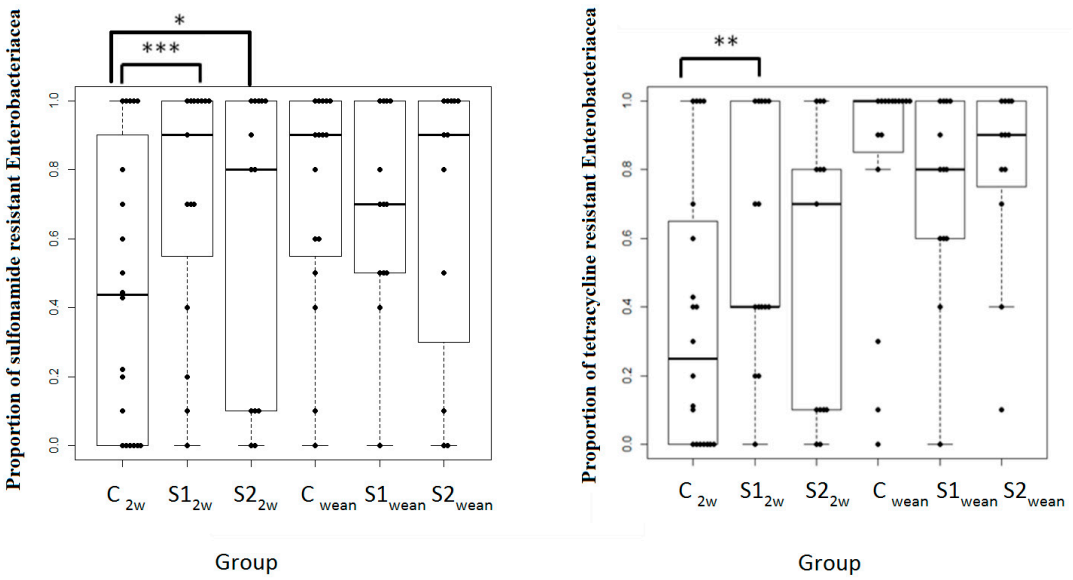

Figure S3: Proportion of Enterobacteriaceae resistant to sulfamethoxazole (left) and tetracycline (right) in piglets at 14 days and at 4 weeks (i.e. weaning). The proportion was measured by counting the Enterobacteria plated on a selective medium and then screening for the antibiotic-resistance of 10 isolates per sample. Stars indicate p-values below 0.05,0.01 and 0.001 respectively. The control piglets are labeled 'C' while the piglets force-fed with the microbial suspensions are labeled 'S1' and 'S2' respectively.

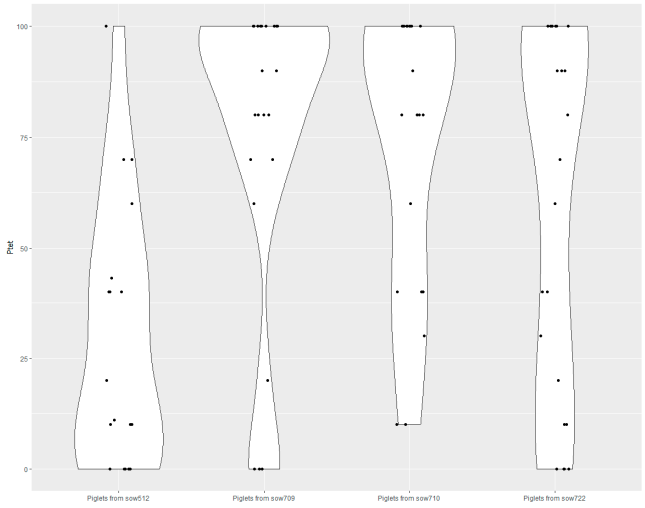

Figure S4 : Lactating sow effect on the Enterobacteriaceae resistant to tetracycline in piglets at 4 weeks (weaning). We used the violin plot from ggplot2 to visualize the impact of the lactating sow at weaning.

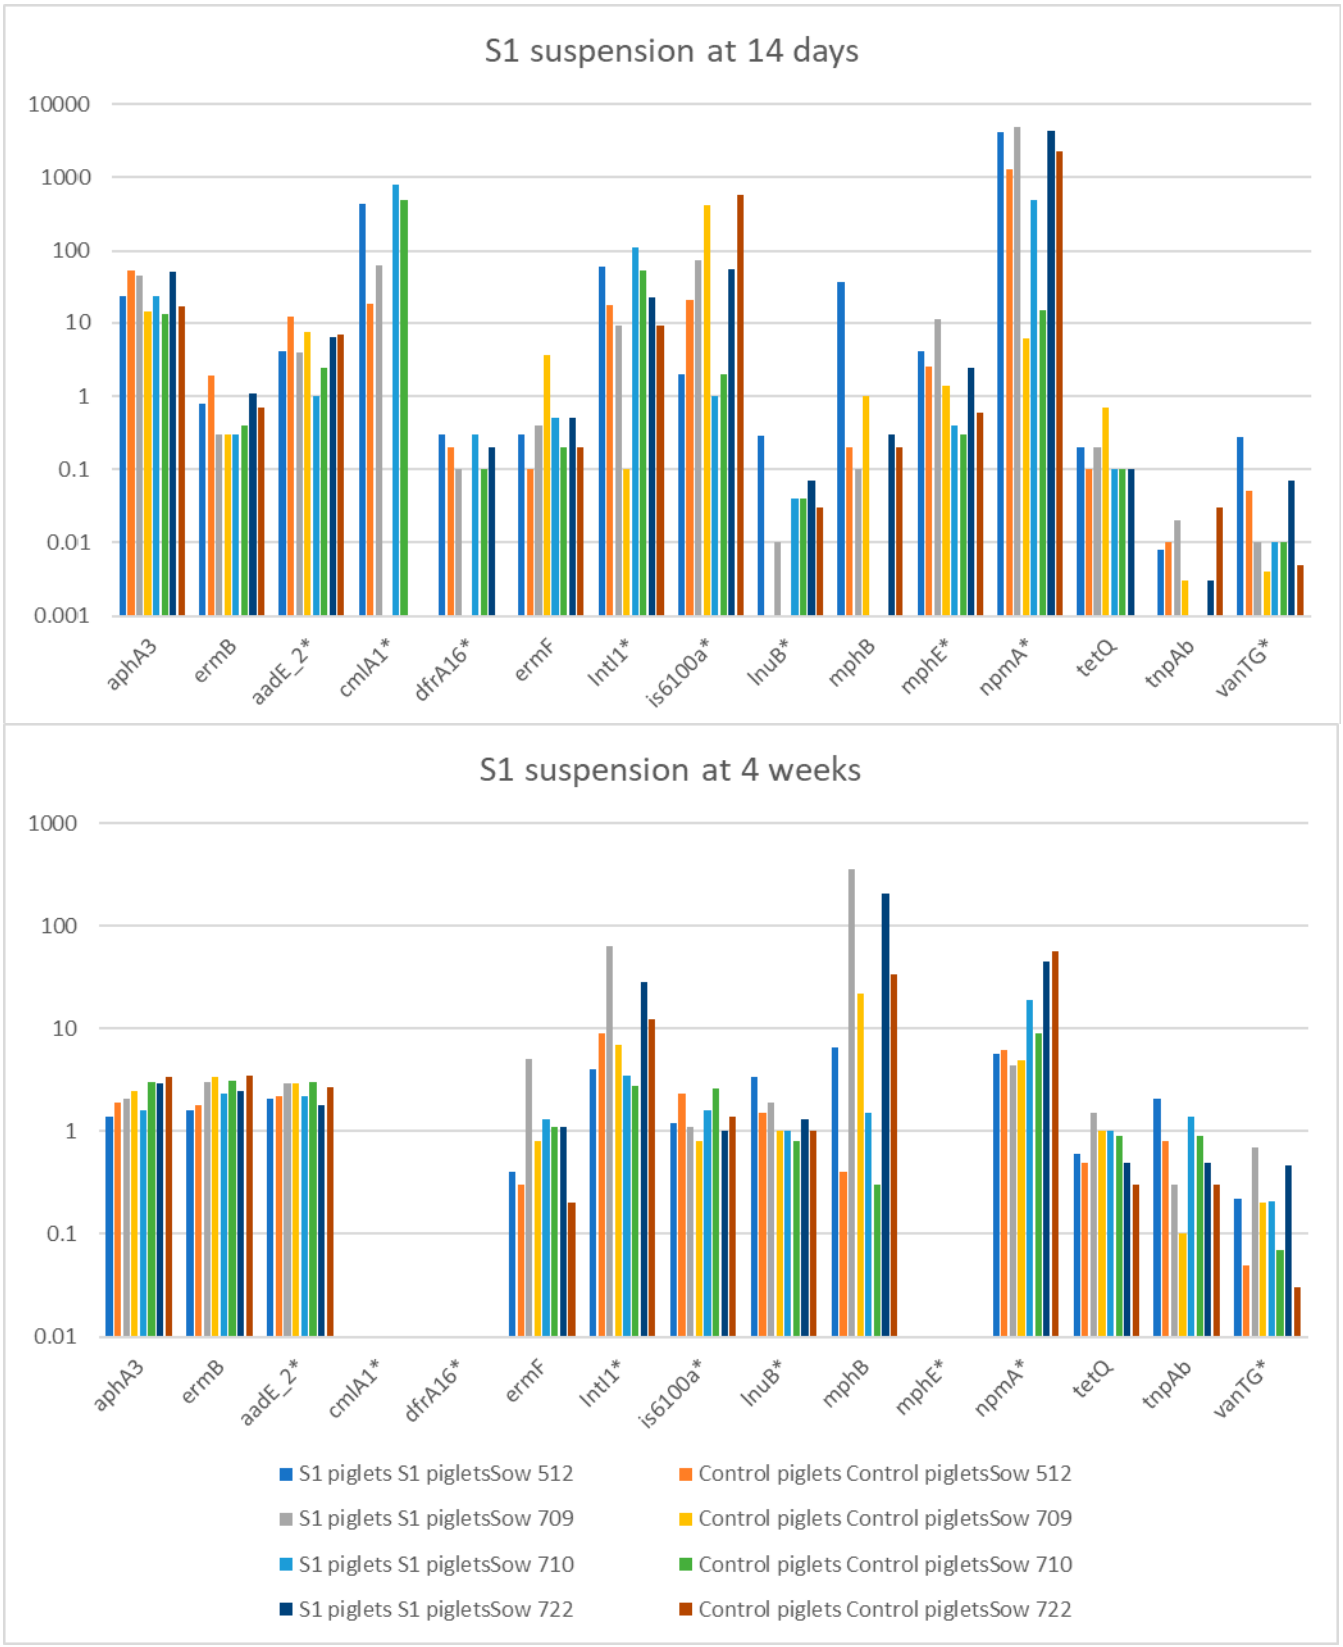
2.2 Graphical representation of the impact of S1 and S2 on ARGs (Fig S5 and S6)



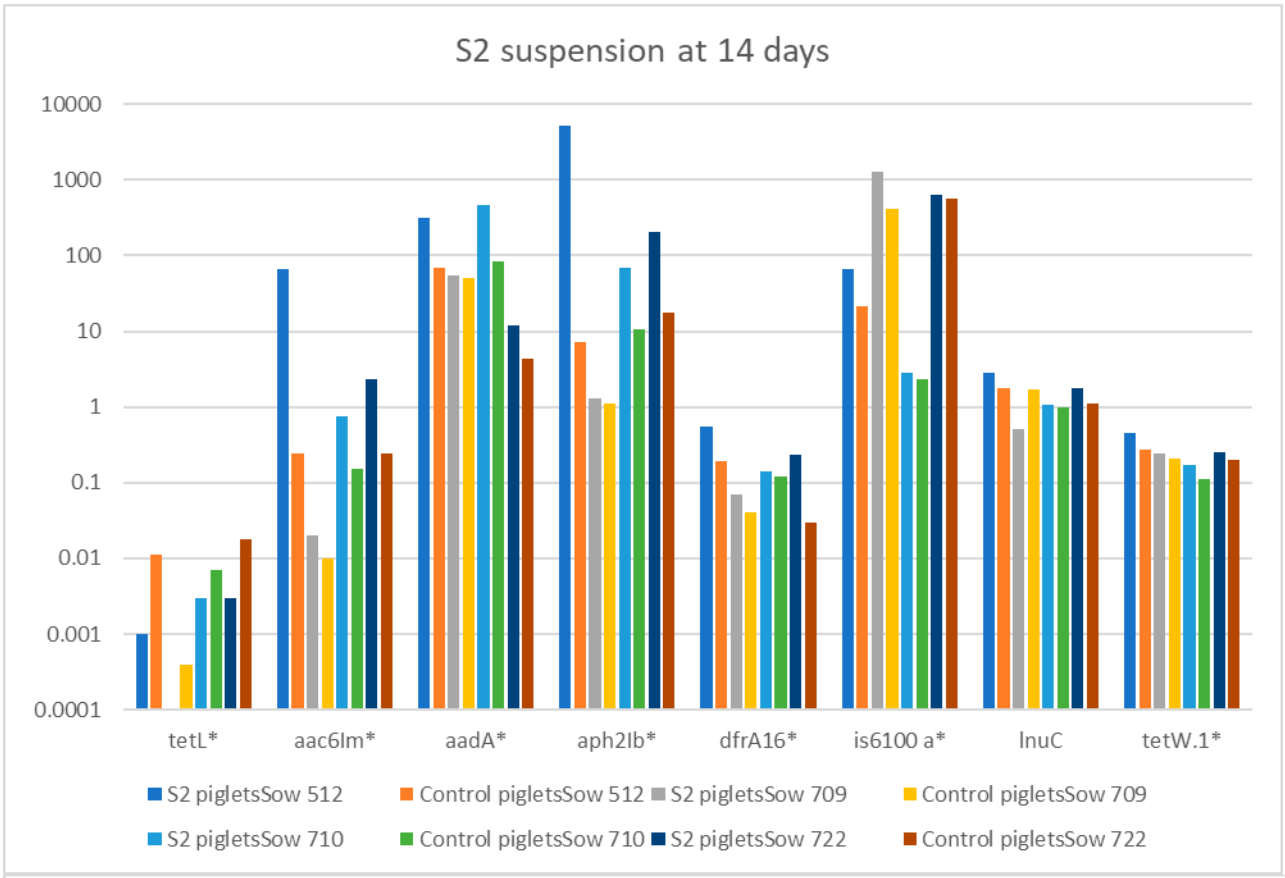


Figure S5 : Graphical representation of the impact of the S1 suspension on ARGs at 14 days and 4 weeks

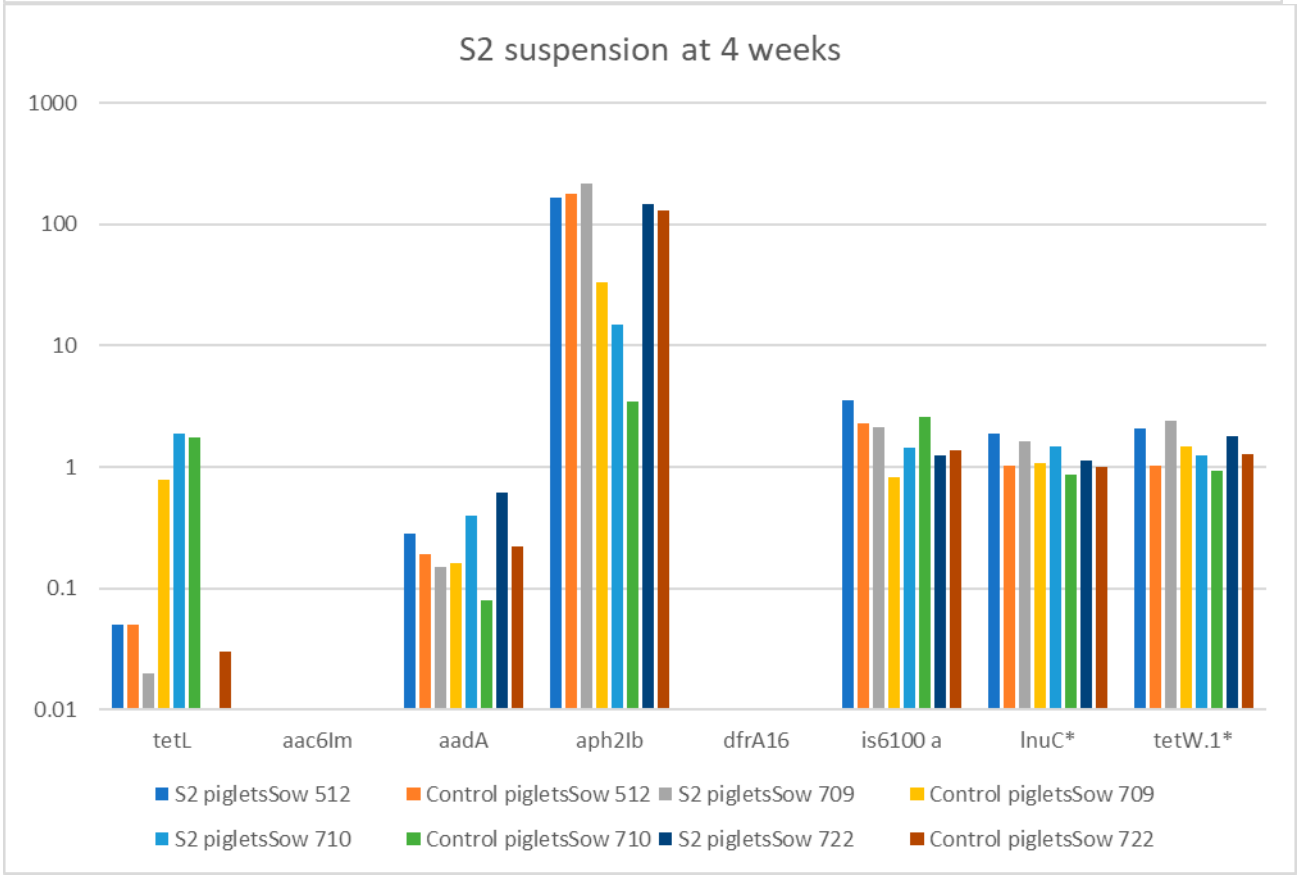

Figure S6 : Graphical representation of the impact of the S1 suspension on ARGs at 14 days and 4 weeks

2.3 Principle of the DAPC

Here we give more detail about the statistics that we used to determine the separation of the gavaged and control piglets via DAPC. DAPC (Jombart et al., 2010) stands for Discriminant Analysis of Principal Components. The first advantage of DAPC lies in the fact that many OTUs are in fact colinear, making them difficult to use in a discriminant analysis. DAPC solves this issue by using a PCA to get orthogonal axes. The second advantage of DAPC lies in the power of the discriminant analysis, which allows to isolate differences that are related to a particular treatment by optimizing the variance between groups while minimizing the variance within groups.

The pitfall of this method is that it will obtain some degree of separation for any groups of individual, especially given the high number of OTUs. The overfitting can be mesured by the a-score, which is the difference between the proportion of successful reassignment and values obtained using random groups. In practice, the p-values corresponds to the proportion of simulation with a better a-score than the 'real' groups. In other words, we performed 1000 simulations with random groups, and we count how many have a better separation than the real observation (i.e. how many a-scores are negative out of the 1000 a-scores obtained). If the separation is due to overfitting, then many simulations will obtain a similar proportion of successful reassignments, leading to many a-scores being negative. In contrast, very few simulations will obtain the a-score of a separation that is not random.

Therefore, the use of DAPC allows us to pool the two sampling dates and the use of a-scores generates an estimation of the statistical significance that takes into account the overfitting. The use of the randomization is close to the rationale of a PERMANOVA. However, in our case the PERMANOVA is not significant (p=0.4) because the major effect is the date of sampling, making the effect of inoculation negligible.

The interested reader is invited to read the initial publication :

T. Jombart, S. Devillard, and F. Balloux, Discriminant analysis of principal components: a new method for the analysis of genetically structured populations. BMC Genet 11 (2010) 94.

2.4 OTUs that separate the piglets are rare in the donor sows (Fig S6)

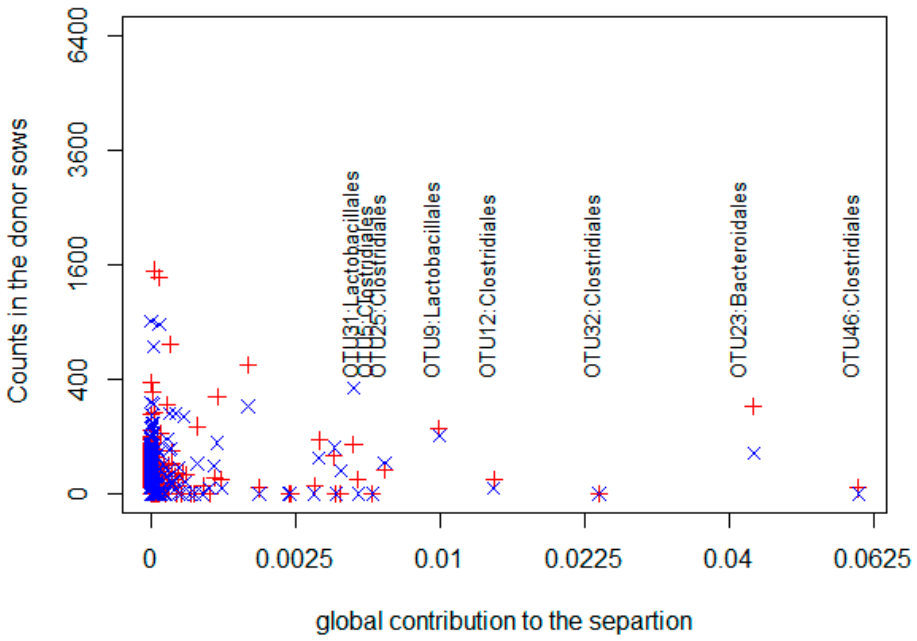

Figure S9: Number of reads of the OTUs in the donor sows by their global contribution in the DAPC. The 8 OTUs needed to significant separation are labeled.

2.5 ARG ratios in the sows and in the S1 piglets at weaning

2.5.1 Table of ARG in S1 piglets at weaning (Table S3)

Table S3 : Significance of the exclusion and relative abundance of targeted genes in the S1 and control piglets at weaning. The abundances are normalized by the abundance of the 16S rRNA gene. The numbers are not between 0 and 1 because the ARGs were pre-amplified whereas the 16S rRNA genes were not (see material and methods). For example the control piglets of Sow512 had up to 33.57/0.42=79.9 fold less mphB than the control piglets from Sow722. The p-values correspond to a 2-way non-parametric Friedman test based on the medians.

2.5.2 Table of ARGs in S2 piglets (Table S4)

Table S4 : Significance of the exclusion and relative abundance of targeted genes in the S2 donor. The abundances are normalized by the abundance of the 16S rRNA gene. The numbers are not between 0 and 1 because the ARGs were pre-amplified whereas the 16S rRNA genes were not (see material and methods). The p-values correspond to a 2-way non-parametric Friedman test based on the medians.

[a] : not an ARG

2.5.3 Visualization of the ARG ratio in S1 and S2 piglets (Fig S2)

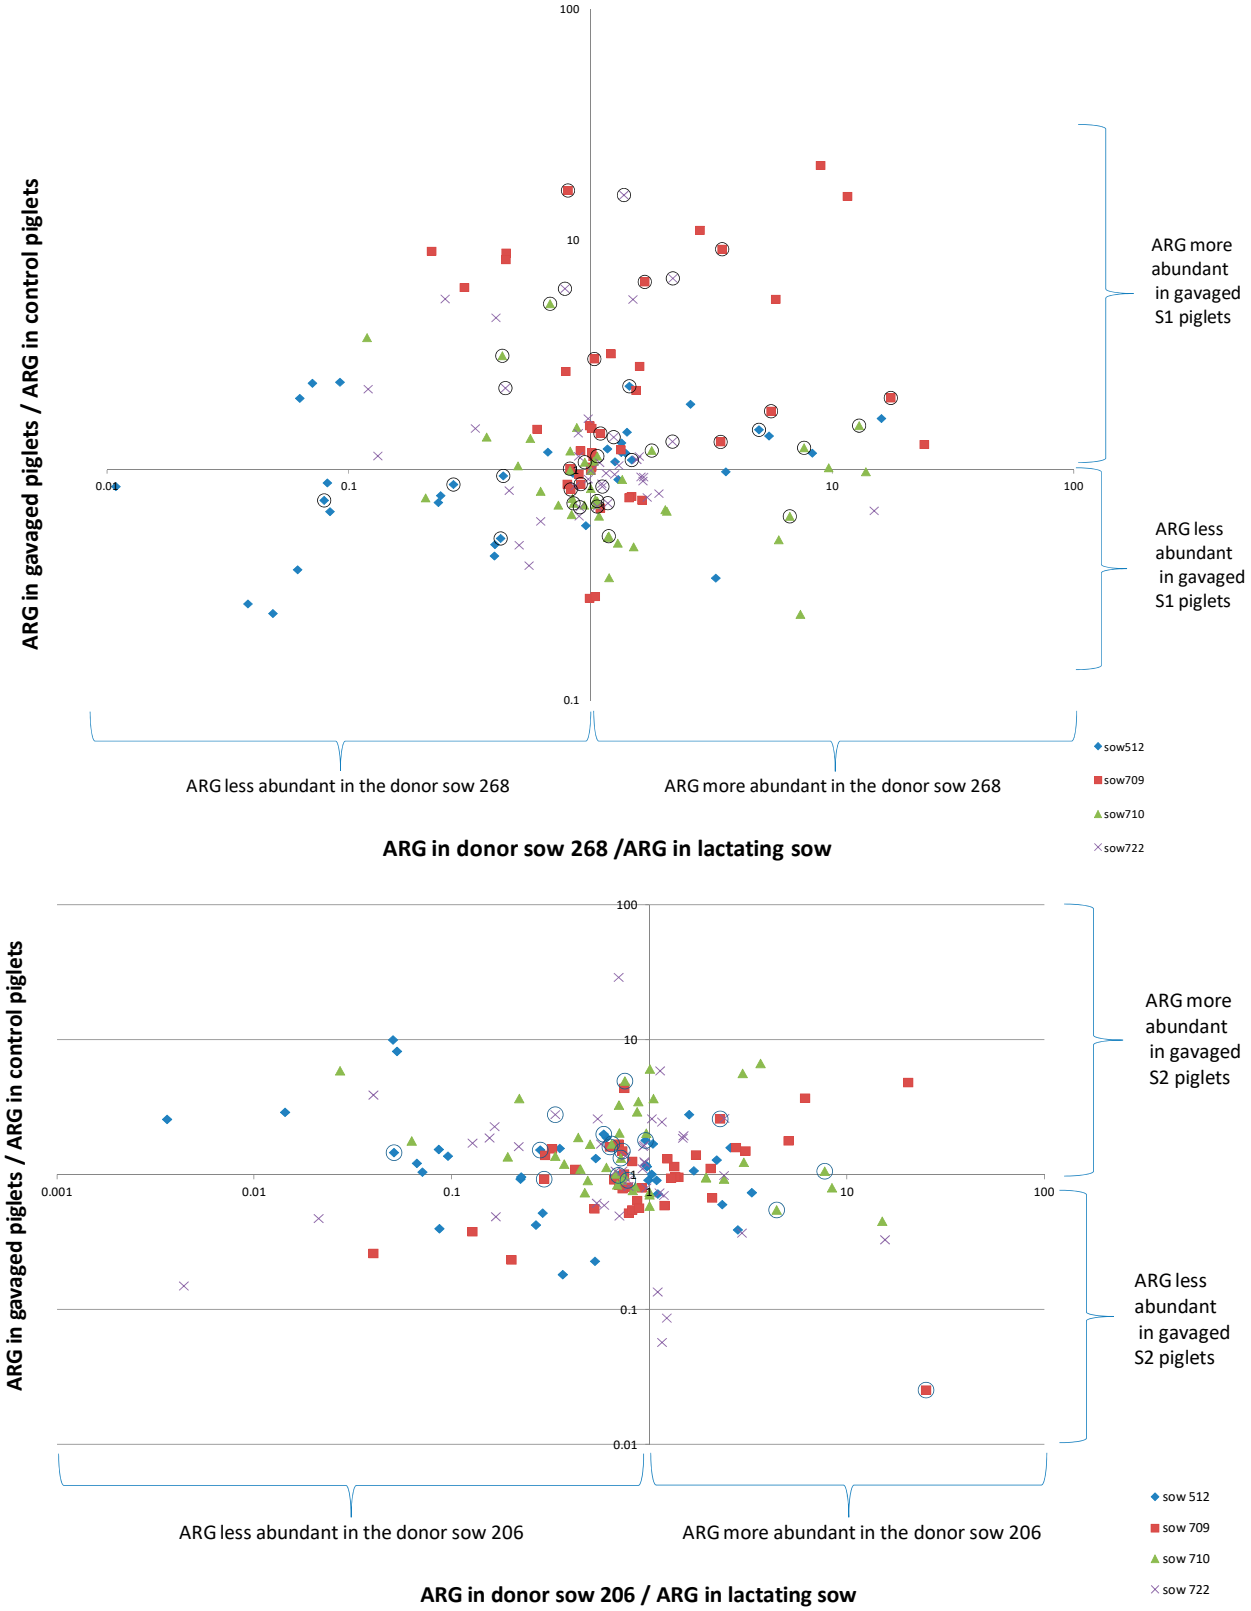

Figure S2: Relative abundance of ARGs in S1 and S2 piglets at weaning (as ratio of the ARG in the control piglets) vs the abundance of ARGs in the donor sow (as ratio of the ARG in the lactating sow). For each ARG in Table S1 (top, corresponding to S1 donor sow 268) or Table S2 (bottom, corresponding to S2 donor sow 206), the X axis indicated the ratio between the relative abundance in the piglets gavaged with suspension

S1 over the relative abundance in the control piglets. The Y-axis indicates the ratio between the relative abundance in the donor sow over the relative abundance in the lactating sow. ARGs that are significantly impacted by the inoculation of suspension are circled. Each sow has a different marker. The axes use a logarithmic scale. The green areas indicate the areas where a low (resp. high) abundance of ARG in the donor translates to a low(resp.high) abundance in the gavaged piglets, i.e the hypothesis that the ARG level in the sows is mirrored in the piglets.
This figure illustrates the challenge of predicting the success of the exclusion based solely on the ARG level in the donor and the lactating sow because a strong ARG contrast is not enough to guarantee a successful exclusion of the ARG.

3. Neutral model applied to the piglets

3.1 Rationale of the neutral model

The rationale of the neutral model is that a metacommunity (microbes surrounding the piglet in our case) feed a local community (microbes in the gut of the piglets). The neutral model assumes that species are 'neutral' in their ecological fitness (i.e. each species has the same growth, death and dispersion rates), and the assembly is the resulting stochastic phenomenon.

The metacommunity can either be objectively measured (such as the microbiota of the milking sow, and the microbiota of the donor sow), or it can be derived from the observation across all the samples. The basic idea is that an OTU that is rare in the metacommunity will be observed in very few local community while an OTU that is abundant in the metacomunity will be observed in every local comunity.

In our case, we first show that the link between the microbiota of the sows and the microbiota of the piglets is tenuous, as most of the OTUs observed in every piglet is not observed in the sows (with identical sequencing depth, Fig S4). We then proceed to fit the neutral model by estimating the metacommunity from the observations across all the piglets (Fig S5). The interested reader is invited to read the publication describing the algorithm fitting the neutral model : A.R. Burns, W.Z. Stephens, K. Stagaman, S. Wong, J.F. Rawls, K. Guillemin, and B.J. Bohannan, Contribution of neutral processes to the assembly of gut microbial communities in the zebrafish over host development. The ISME journal 10 (2016) 655-64.

3.2 Necessity of estimating the metacommunity from piglets (Fig S8)

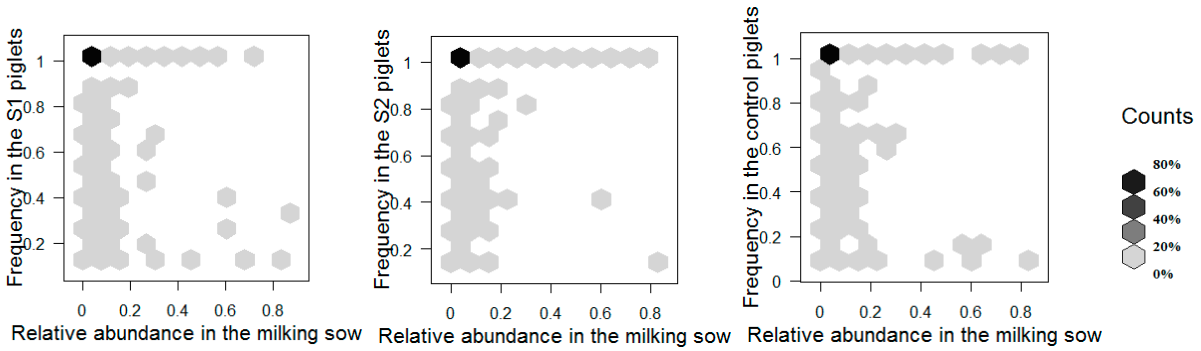

Figure S8: Repartition of the frequency of the OTUs in S1, S2 and control piglets compared to the abundance of the OTUs in the lactating sows. Each OTU is plotted with its abundance in the milking sow (X-axis) vs the number of piglets in which it was observed across the 4 lactating sows (i.e. out of 3x4 piglets for S1 or S2, out of 4x4 piglets for the control) (Frequency on the Y-Axis). The area was divided in hexagons with the hexbin package of R, and the density of each hexagon was color-coded. This figure shows that the piglets gavaged with S1, S2 or saline water all had more than 80% of their OTUs that were present in every piglet, yet undetectable in their milking sow sampled at the same sequencing depth. This contrast is in clear opposition with the idea that the milking sow provides a metacommunity that colonize the gut of the piglet following a neutral model (at least in the control piglets), and justifies the use of an extrapolated metacommunity to fit the neutral model on the gut microbes of the piglets (Fig.2).

3.3 Fitting the neutral model to control, S1 and S2 piglets of sow722 (Fig S7)

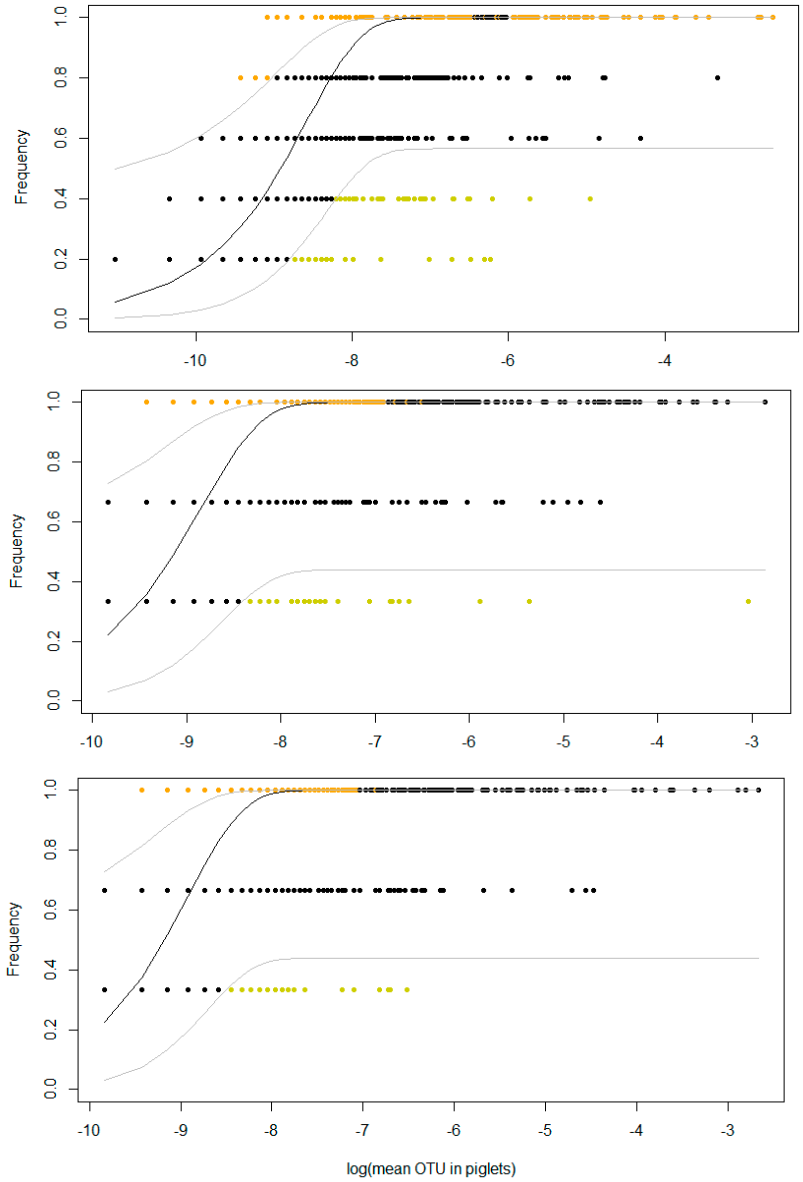

Figure S7 : Fitting the neutral model to control, S1 and S2 piglets of sow722. The controls piglets (TOP) show an acceptable fit (R^2=0.45) while piglets force-fed with S1 (MIDDLE) and S2 (BOTTOM) are not well described by the model (R^2<0.04). OTUs more frequent than expected are in orange, OTUs less frequent than expected are in green. The lack of fit of the neutral model for the gavaged piglets (in contrast to the control piglets for which the neutral model offers a decent fit) indicates that the inoculation of microbial suspension in the early life modified the rules of assembly of the microbial communities.

4. Linking OTUs and ARGs

4.1 Rationale of the MINE method

In our dataset, we merged the data of ARG abundance and 16S gene for each sample. We then look at the relationships between ARG and OTU using the MINE software (see Material and Method section), which can detect simultaneously linear and non-linear relationships. The linear and non-linear relationships between the selected OTUs and ARGs were characterized on a filtered OTU table so that the total count of each OTU across the samples is higher than 1000 (i.e., 0.07% of the total counts), which was merged with the ARG dataset using the sample Id. We then computed the maximal information coefficient index using the application provided with Java SE 1.7.0_02[49] with the percentage of the records necessary to have data in them for both variables before those variables are compared (cv) and the exponent (α) parameters set to 0.6.

To keep only relationships that are statistically significant, we used the same randomization strategy as for the DAPC. Indeed, the empirical null distribution of the maximal information coefficient was computed using 1000 random permutations of the relative abundances within the variables in order to account for the baseline correlation bound to occur between any two vectors. The maximal value of the null distribution was set as the significant threshold for the real dataset, i.e., the dataset before randomization. The relationships were labeled as linear when the regression coefficient was higher than 0.5. They were labeled as non-linear when the regression coefficient was negative and the nonlinearity coefficient was higher than 0.3 (see Fig S7 for examples). The dataset at 14 days and the dataset at weaning were analyzed separately to avoid relationships due to the impact of age.

4.2 Examples of ARG-OTU relationships (Fig S10)

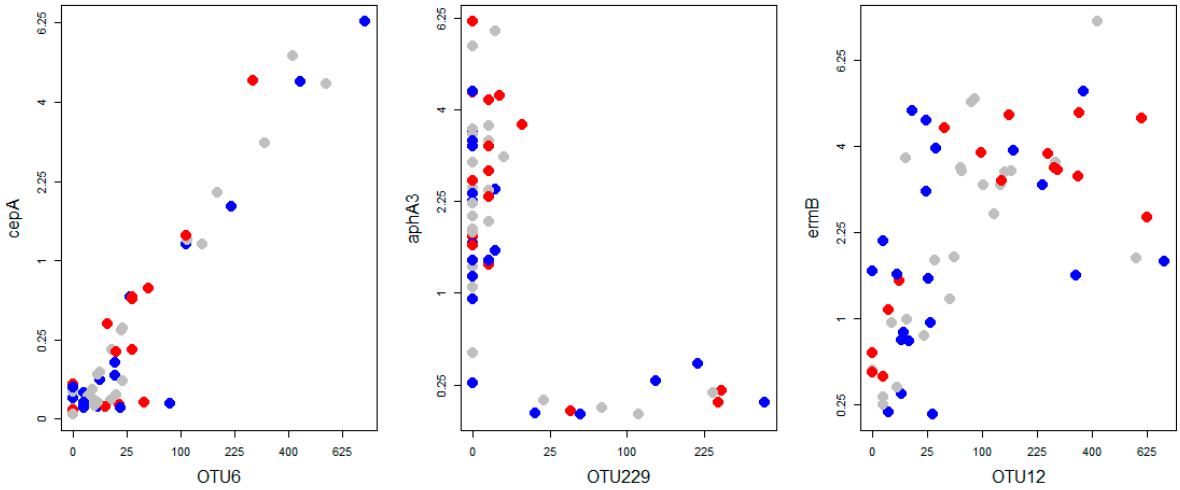

Figure S10: Representative relationships found between OTUs and ARGs for linear (left), co-exclusion (middle), and uncharacterized (right) relationships. The X-axis indicates the number of counts of the OTU and the Y-axis reports the quantification of the antibiotic resistance gene. The points are color-coded for their groups (Red : S1 piglets, blue : S2 piglets, gray : control piglets)

4.3 Distribution of the MIC under real and randomized conditions (Fig S11)

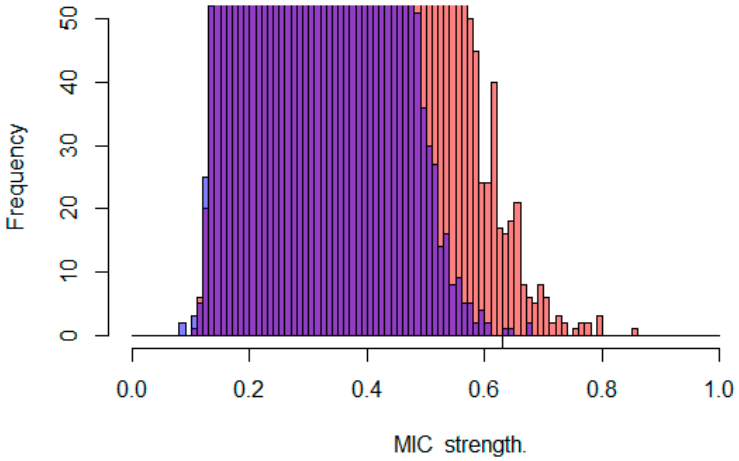

Figure S11 : comparison of the distribution of the maximal information coefficient index in the dataset before and after randomization. The maximal value of the null distribution was set as the significant threshold for the real dataset, i.e. the dataset before randomization (red). The rationale is that the MIC values that were never observed in the randomized dataset (blue) are not an artifact due to the high number of pairwise comparison.

4.4 Network of ARGs and OTUs at weaning (Fig S12)

The statistically significant interactions between ARGs and OTU, i.e. the interactions whose MIC was never observed in the randomized dataset (see List above) are represented below using Gephi 0.9.2.

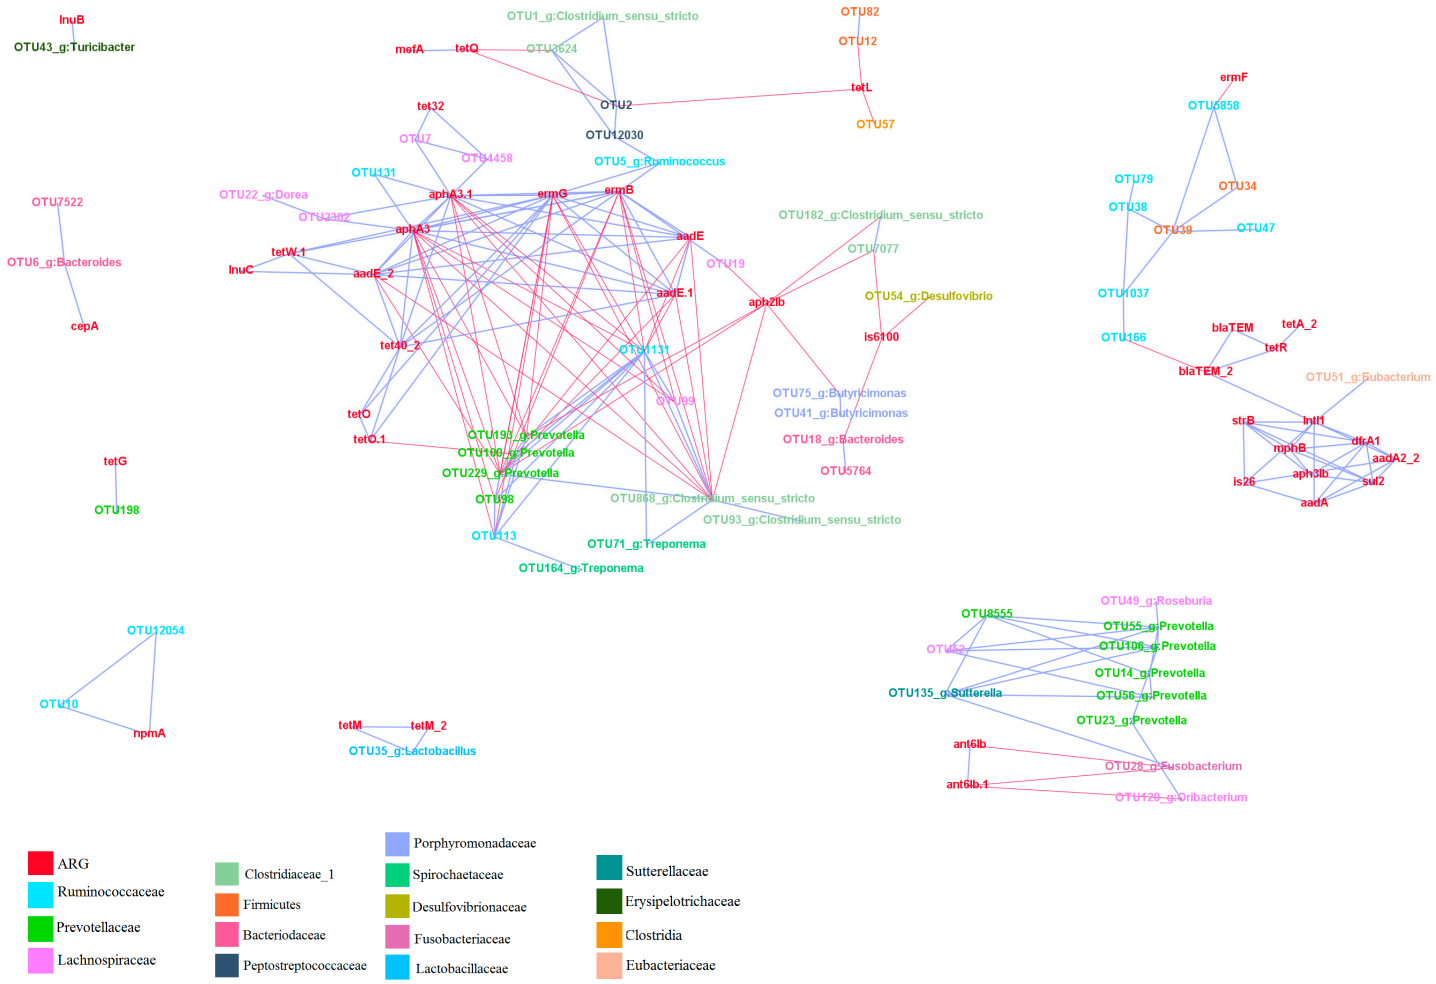

Figure S12 : Network of significant ARGs and OTUs relationships at weaning (excluding relationships between OTUs that were not linked to ARGs at all). The network representation of the non-linear relationships as assessed by the MIC, in which ARGs are indicated by their name in red, OTUs are represented by their number and color-coded by their order. The linear clusters in which at least one ARG is present are represented in blue, and co-exclusive relationships between ARGs and OTUs are represented in red.
