

Figure S4: Analysis of the proteomic results obtained on J774A.1 cells after a 10 days exposure to silica by the non-metric multidimensional scaling approach. CTL: control, cells without nanomaterials, Pr: precipitated silica 220 m²/g, Fu: fumed silica 200 m²/g. The results show that 1) the groups are consistent (no interpenetration of the groups) and 2) that precipitated silica induced more changes of the proteome than fumed silica.
