Figure S1. Linear regression (1.dashed lines), Phylogenetic Generalized Least Squares (PGLS) method (1. continuous lines) and “crunch” method (2) for the relationships between genomic variables, with all species (black), excluding the species of Chlorophyta (red) and excluding the species of Streptophyta (green): (A) The effect of the log transformed number of repeated sequences (NRS), on non-coding genome (%NC); (B) Effect of %NC on log transformed Genome length (GL); (C) Effect of log(NRS) on GC content (%GC); (D) Effect of %NC on %GC; (E) Effect of the number of protein-coding genes (NPG) on the log(GL).

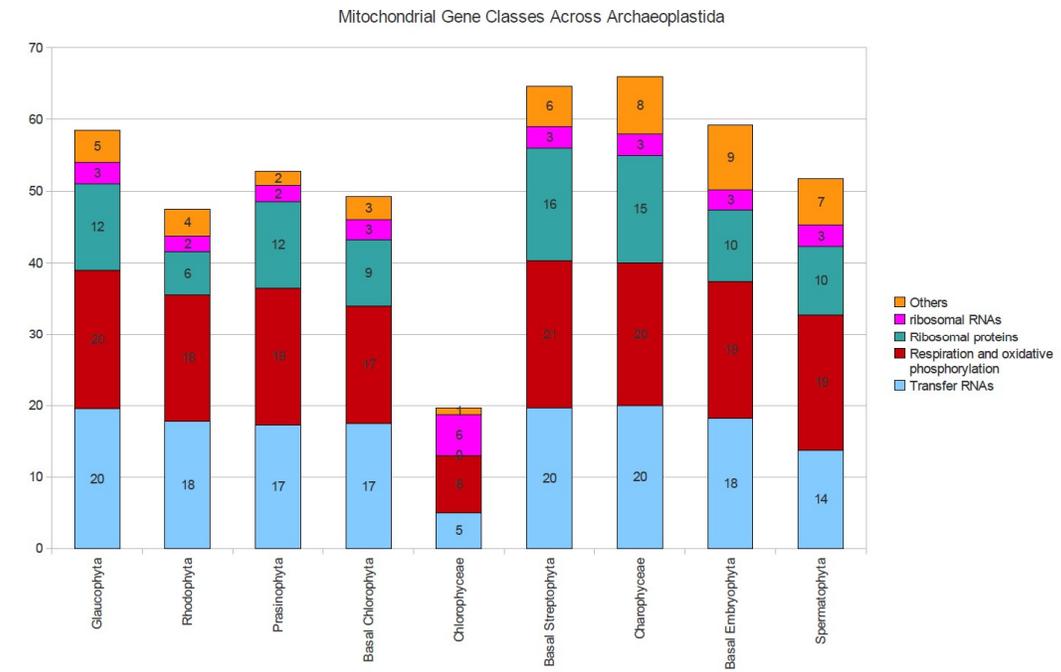

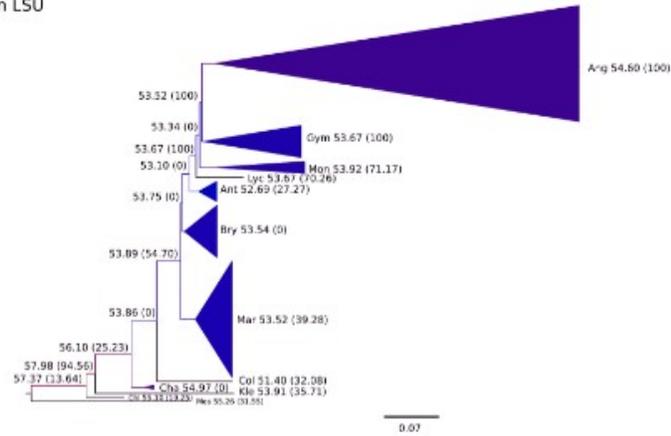

Figure S2. Mitochondrial gene classes across Archaeplastida. Average gene number for each function in each clade.

Mitochondrion LSU

Chloroplast LSU

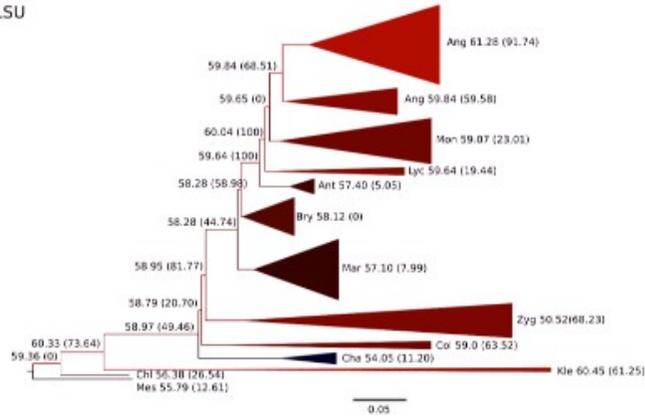

Figure S3. Evolution of GC content and GC* across the phylogeny of Streptophyta: A) Mitochondrial ribosomal LSU; B) Plastidial ribosomal LSU. Values correspond to ancestral GC content at nodes, or GC* (equilibrium GC content) in parentheses. Colors in terminal branches represent average GC content (blue: lowest GC content; red: highest GC content). The color scale is relative to the data set in each tree and is not directly comparable between them. List of species and GC content at terminal branches of each ribosomal subunit is available in Supplementary Table S3.
