Detailed Simplified scheme of related molecules in Stage 1

During the biosynthesis of hispidin, adenosine triphosphate-magnesium ion complex (Mg-ATP) and CoA are involved in the reaction, which contain many atoms and greatly raised the complexity of calculation. To solve this, we only reserved the key reaction positions in theoretical research, and the rest parts were simplified according to the principle that the pK_a values of substituted conjugated acids are similar. The most critical reaction site in MgATP is the first phosphate linked to adenosine, while magnesium pyrophosphate ion complex (Mg-PPi) plays the role of leaving group in the reaction. The Mg-PPi tends to exist in the form of $MgHP_2O_7$ [1]. Because the pK_a value of $MgH_2P_2O_7$ ($pK_{a1}=4.4$, $pK_{a2}=6.6$) is similar to that of CH_3COOH ($pK_a=4.75$), the part of Mg-PPi in Mg-ATP can be simplified to CH_3COO [2], as shown in Scheme S1. After the leaving of Mg-PPi, the remaining adenosine monophosphate (AMP) still acts as a leaving group and has a large number of atoms, which is not directly related to the reaction process. As the pK_a values of AMP ($pK_{a1}=3.8$, $pK_{a2}=6.2$)[3] and dihydromethyl phosphate ($pK_{a1}=2.2$, $pK_{a2}=7.9$)[2] are similar, adenosine can be simplified as methyl. Therefore, as shown in Scheme S2, in the quantum chemistry calculation, acetyl methyl phosphate, a simplified calculation model, is used to simulate the behavior of Mg-ATP in the actual reaction process.

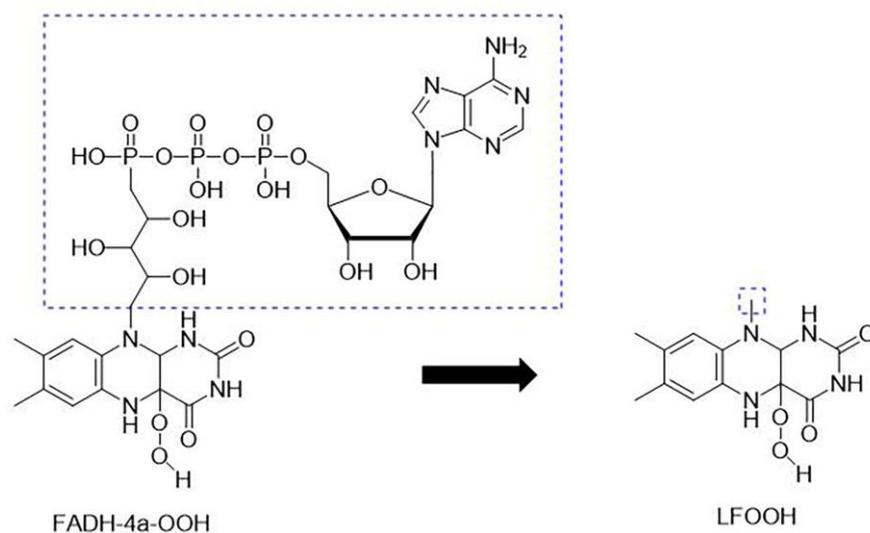

Scheme S1. Simplification strategy of the calculation model of MgATP

After CoA and caffeic acid are combined, caffeoyl-CoA achieves the growth of carbon chain through condensation reaction, which involves the process of transferring caffeoyl from CoA to cysteine. This progress is called loading of substrate. Whether CoA or cysteine, it is the sulfhydryl group in the molecule that actually involved in the reaction. The large volume group linked to sulfhydryl group in CoA and cysteine do not actually participate in the reaction process, and the pK_a values of sulfhydryl group in CoA and cysteine are 9.83 and 10.3, respectively[4, 5, 6, 7], while that of sulfhydryl group in methyl mercaptan is 10.3[3], so large groups in both molecules that link to sulfhydryl groups can be simplified as methyl, that is, CoA and cysteine could be simplified as methyl mercaptan. The pK_a value of sulfhydryl group has little change before and after the simplification of the model, which indicates that the simplification method is reasonable.

Scheme S2. Simplification strategy of the calculation model of CoA and cysteine.

The 3-hydroxylation process of hispidin involves flavin peroxide (FADH-4a-OOH), and the long phosphoribosyl side chain in its molecule is not directly involved in the process. Therefore, as shown in Scheme S3, this part is replaced by methyl in the calculation, that is, FADH-4a-OOH is simplified as peroxide of lumiflavin (LFOOH). The rationality of this simplified way has been confirmed by theoretical simulation of other flavins participating in the reaction,^[8] and imidazole cation or neutral imidazole molecule is introduced to simulate the proton donor or proton acceptor near the reaction center. When studying the proton transfer process in substrate molecules assisted by hydrogen bond network in the environment, water molecules were introduced as water bridges.

Scheme S3. Simplification strategy of the calculation model of flavin peroxide
