Message from the Guest Editor

Dear Colleagues,

The present Special Issue aims to summarize new evidence on the role of biological systems interacting with dopamine and other neurotransmitters implicated in the occurrence of psychotic symptoms and treatment responses. The role of stress hormones and other hormonal compounds in the clinical presentation (phenotype) and response to treatment will also be explored. Evidence for the effectiveness of pharmacological and non-pharmacological interventions to treat schizophrenia and related disorders is also welcome, with a special emphasis on treatments targeting emotions and cognitive symptoms. The impact of physical health on psychotic symptoms and vice versa is also a topic of interest in psychotic populations.
